Create and post cost invoices in Agrio

Last modified: 2023-01-31

Introduction

In Agrio there are different types of invoices. There is a distinction made between product invoices, which are invoices directly related to the products purchased (and later on sold), and cost invoices, which are not directly related to a product, but can be linked to multiple products or they can be general costs for example for furniture or maintenance. This document focuses on purchase cost invoices. It describes how these are created, posted and explains how the invoices can be divided over multiple transports which the invoice relates to.

Purchase Cost Invoices

Purchase cost invoices can be created manually in Agrio. It is also possible that cost invoices are sent by the vendor, than it is possible to automatically recognize, capture and import these invoices by use of Document Capture.

Creating a Purchase Cost Invoice in Agrio

When creating a Purchase Cost Invoice in Agrio manually the user has to fill in the data. It can be that for example an invoice is received for some small office furniture. The company in this example that is receiving the invoice does not use Document Capture. This means that the administration department has to create the invoice manually in Agrio. It has to fill in different data on the invoice:

1. Cost Invoice Type: here can be determined what type of cost invoice it is. So you are able to make a distinction between different cost invoice types. It is also possible to assign a separate number series to the different Cost Invoice Types. This helps to make a better distinction between the cost invoice types.
2. Vendor: here the vendor of which the invoice was received has to be selected.
3. Line Type: define what type of invoice line it is and select for example G/L Account. Then the right G/L account for posting the purchase cost invoice can be selected.

4. Cost Type: define what kind of “cost type” it is. For example, packaging, other, transport. Per Cost Type is be defined how the costs are split. For example per weight, gross weight, packaging 1, packaging 2.
5. Input Price: fill in the price per input unit of measure in this example per piece
6. Status: the invoice can have different statuses. It can be open, pending for approval (if approval workflows are setup), released, posted.

Total Incl. VAT (EUR): here the total amount including VAT (if applicable) are shown of all the invoice lines together.

Under the amounts on the invoice other details can be filled in. For example the details for invoicing, bank account used, bank account of the vendor, payment terms. Another tab presents shipping and payment details and another tab presents Foreign Trade specifications.

Posting the Invoice

When the invoice is correctly filled it is possible to post the invoice. Here the button “Post” has to be selected in the ribbon under “Posting”.

When opening the Posted Invoice, it shows that the Purchase cost invoice is approved before posting (1). Also the related entries used during posting can be shown, therefore “navigate” (2) has to be selected under the button “actions” in the ribbon.

Assigning Costs

Assigning costs to transports

It is possible that a purchase cost invoice for freight/transport cost is received from a vendor. The cost can be assigned to transport(s) it relates to. When the button “assign cost” (1) is selected in the ribbon above the purchase invoice line a new screen with all the transport lines will open (2). Here the right transport line(s) can be selected and the cost are divided over the selected transport line(s). It is possible to assign the cost to several transport orders, then the total amount is divided over the various transport lines

on the basis of kilos (depending on setup of cost type).

On the transport line overview it is now visible that additional cost are assigned to the transport. This can be used for reporting/statistics to see the cost related to the transport and the profit remaining.

Assigning cost to pool

Besides assigning cost to transport(s) it is also possible to assign the cost to a pool. On the purchase invoice line the right pool code can be selected. When this is selected and the invoice is posted the cost on the invoice are included in the pool. This affects the pool and the cost are divided over the pool. This helps to get all the revenue and cost into the pool to make the most accurate pool settlement.

Box Allocation

Last modified: 2023-01-26

Introduction

Growers sometimes choose to combine their lots into one lot. This may be convenient for various reasons. In AGRIO Software, the functionality to support this is called 'Box allocation'.

Another reason for using the functionality 'Box allocation' is for easy administration within AGRIO Software. A lot may consist of multiple plots and one plot is one lot number in AGRIO Software. So, if a lot consists of six plots, then the grower will have six contract lines in AGRIO Software. If all of those six plots end up having the same qualities and classes, then an AGRIO Software user may group them together into one lot with 'Box allocation'. The grower will receive only one sorting order instead of six sorting orders.

This document explains the functionality of Box allocation.

Box Allocation

Box allocation in AGRIO Software are fairly straight forward. A user creates a purchase contract with multiple lines. Afterwards, these lines may be allocated to boxes. In the example below, a contract with three lines is created. The lines together have a total of 6 hectares.

Figure 1 Purchase contract with three contract lines

When the contract is setup correctly, the user may click on Place in Boxes in the menu (See image above). A screen opens with a couple of possibilities. Fill in the column 'New Box No.' to allocate contract lines to a certain box. In the example below, all three lines are allocated to a box with no. 1. You may choose to create multiple boxes with different numbers. Click on 'Automatic Box Numbering' if you want the contract lines to be allocated automatically. The system will allocate each line to a different box no. The numbers can be overwritten manually.

To allocate contract lines to boxes:

- The contract must have the status 'Open'
- Own use must be empty on each contract line

It is advised to only allocate lines with the same class, the system will give you a notification if the class is different. If classes are different, the system will take the lowest class for the new Box.

Figure 2 Box allocation

Once the box numbers are configured correctly, the button 'Process proposal' will allocate the lines into the box. If you want to undo the box allocation, select the Boxed line and click 'Undo Joined Box Allocation'.

- Undoing a box allocation is not allowed if any Process Orders exist on the Boxed contract line.

Figure 3 Boxed line

The lines that are allocated to a box are replaced by the 'Boxed' contract line. Review the values of the newly created Boxed contract line carefully. Most of the values will have been taken over from the Contract Type Code.

Figure 4 Boxed contract line

If you want to review the lots that are in the Boxed contract line, navigate to the Lot Card and review the section 'Box'. Here, you can find the 'Source Lot Count'.

Figure 5 Lot Card with Box information

Some additional notes on Box allocation:

- The Boxed contract line will have received the weighted average in sizes of all the lots within the box.
- On a Boxed contract line it is possible to create Box Samples. Test digs however, are not possible on a Boxed contract line.
- When using the Dutch NAK import, a notification will be shown to the user if a contract line that was allocated to a Box was lowered in class.

Initial Purchase Position

Last modified: 2023-01-19

Introduction

The “lot inventory list” is one of the most extensive and valuable screens in Agrio. It shows the quantities available, where the quantities are located, what the sizes are and other important information about the different lots. In the beginning of the season the purchase contracts are created. By creating these contracts, lots are also created in Agrio and the quantities of the lots become visible in Agrio. In the beginning of the season it shows the initial purchase position, which means that this are not the exact quantities, but an estimation in the beginning of the season based on prefilled data. This topic described the “Initial Purchase Position”.

Determination of the Initial Purchase Position

The initial purchasing position per variety in AGRIO Software is determined on the basis of the purchasing contract. If purchases are made in hectares, this is automatically converted to the base unit, normally kilograms. The lot inventory shows the purchase position per actual purchased size. For example, if 100 tons of field crop (00/99) in JUTE25 are purchased, it looks like this:

Figure 1 Initial purchasing position

When a lot is created (by releasing a purchase contract), the purchased quantity is also automatically distributed over the virtual stock sizes (5mm sizes). The standard distribution is used for this, which is recorded in AGRIO Software at the beginning of each harvest year. See below an example of the size distribution for a specific harvest year. This size distribution is used to determine the quantities per 5mm size of a new lot which is created by a purchase contract.

When opening the lot card of the purchased lot, you will see how many kilos of the certain sizes are expected to be available.

When opening the Variety Statistics overview, the lot is shown including the position (planned), (position after reservation), sizes etc.

Changes during the Season

During the season, the position will change as a result of multiple activities. The quantities are updated based on performed test-digs, box valuations, samples taken or more quantity is added on the purchase contract line. Also the quantities become less during the season when these are transported to end customers. In the beginning of the season also reservations can be made on different levels, see topic “forecasts & reservations” for a detailed explanation.

If for example from the purchased lot CP-IPT21-0036 (see graph 1) a partial delivery is made of 12.000kg to an end customer the position will be updated. When the partial delivery is created and for the end customer and the lot selection is done (including process order if needed) the partial delivery can be set to status “release”. On the lot inventory you will see that the “Position” remains 100.000kg because the quantities are still at the growers location. However the 12.000kg is selected on a partial delivery, so the “purchase open (Planned)” and the “Position (planned)” becomes 88.000 as can be seen in the graph below. This to avoid that the same quantities/potatoes are selected on multiple partial deliveries, leading to partial deliveries that cannot be finished. Because the required quantities are not available anymore at the growers location, as these were already shipped to another end customer with another partial

delivery.

When opening the variety statistics of the lot CP-IPT21-0036 you also see that the planned position is not 100.000kg anymore but 88.000kg

When the 12.000kg is delivered to the end customer, the partial delivery is finished. This also affects the position. The position now becomes also 88.000, because the quantities are not on the growers location anymore but are on the location of the end customer. This means that these quantities are no longer part of the position of the lot CP-IPT21-0036.

As earlier mentioned, the quantities will change during the season as a result of different activities.

Surplus

Last modified: 2023-01-26

Surplus

AGRIO Software is familiar with three stages of estimating the yield per hectare during the purchase contracting stage of the season. These stages are:

1. Season average yield calculation
2. Test digging yield calculation
3. Box valuation yield calculation

The season average is the first estimation that is done in AGRIO Software. A test dig or a box valuation will change that first figure. Since purchasers may have created contracts based on that first figure, the season average, they may want to know what the new yield estimation is relative to the season average. With that information, purchasers may want to adjust the contracts. The difference in yield relative to the season distribution is called the 'Surplus' in AGRIO Software.

Purchase Contract

When creating a Purchase Contract, AGRIO Software will determine the initial expected yield. This yield may also be referred to as the season average. Users may setup expected yields per hectare in the segment setup. In the example below, the expected contracted yield for one hectare in 3060mm is 26.250kg. Because this is the initial calculated value, the Surplus is 0.

Figure 1 Purchase Contract with Season Average

When a test dig is applied, the expected yield is changed. In the example below, the expected yield has changed from 26.250kg to 30.666kg, due to the Test dig. This means an increase of 4.416kg relative to the initial expected yield. Therefore, the Surplus has now changed from 0 to 4.416kg. The same functionality applies to the Box valuation.

Figure 2 Purchase Contract with Test dig

The Surplus only changes when Test digs or Box valuations are applied. If a purchaser wants to change the contracted yield per hectare, he can modify the column 'Yield per UOM – Contracted'. Changing this column will change the Surplus accordingly. In the example below, the Yield per UOM – Contracted has changed to 28.000kg. The Surplus has automatically recalculated to 2.666kg.

Figure 3 Purchase Contract with 'Yield per UOM - Contracted' changed

Visibility of the Surplus

The Surplus can be reviewed in a couple of AGRIO Software screens. They are listed below.

Country Requirements

Last modified: 2023-01-26

Country Requirements

In Agrio Software, it is now possible to apply Country Requirements to Shipments and Production Orders. These Country Requirements may differ from the actual Unloading Country. This document shows how to apply the Country Requirements.

The Country Requirements are applied to the following screens in Agrio Software. If the field is not visible, it can be added to the screen using Personalization.

- Sales Contract Card > Lines
- Sales Contract Lines (Menu)
- Customer Card
- Process Order Lines (Menu)
- Process Order Card > Production Lines
- Partial Delivery Lines (Menu)
- Partial Delivery Card > Lines
- Transport Order Card > Lines
- Transport Lines (Menu)

Setup

Segment Dependent Setup

The Country Requirements are defined in the Segment Dependent Setup, Master data no.122.

Link a Country Requirement to a Country Code so that Agrio Software can automatically determine based on Country Codes, what the Country Requirement may be. You may define multiple Country Requirements with the same Country Code.

Agrio Software will select the first Country Requirement it can find using the Country Code, the user can override the selection manually.

Figure 1 Setup Country Requirements

Customer Card

The Country Requirements Country Code may be applied on the Customer Card. Once applied, the information will follow through to the Sales Contracts.

Usage

Sales Contract

The Country Requirements are added to the Sales Contract Lines automatically if the masterdata is filled on the Customer Card. The user can override the Country Requirements for each Sales Contract Line automatically.

Figure 2 Sales Contract Lines

Partial Delivery

When a Partial Delivery is created from the Sales Contract or Sales Contract Line, the Country Requirements are adapted to the Partial Delivery Lines automatically. The user can override the Country Requirements if necessary.

Figure 3 Partial Delivery

When a Partial Delivery is created manually from the menu, the system will derive the correct Country Requirements from the Sales Contract Lines when the Sales Contract Lines are selected.

Transport Order

When the Sales are selected on the Transport Order, the Country Requirements are adapted to the Transport Lines automatically. The user can override the Country Requirements if necessary.

Forecast & Reservations

Last modified: 2023-01-31

Introduction

In AGRIO the term forecast is used to indicate what quantity is expected to be available (purchase) or requested (sales) in the harvest year to which the forecast refers. Multiple versions of forecasts can be entered for a harvest year. Within AGRIO the reservation module is an important functionality to ensure that the demand of the customer is covered by the supply of the vendors and that the availability of the inventory is insightful. This prevents the situation that a lot is promised to multiple customers while the quantity is not sufficient. Reservations that are made are also visible in the forecast that has been made. This document will explain these functionalities in more detail.

Setup

Different settings are applicable in Agrio to meet the demands of the company with regard to the reservation module. The following settings should be defined, depending on the needs:

- Agrio setup
- Segment Card
- Agrio permissions
- Target and Source Groups
- Reservation sizes
- Forecast

Agrio Setup

At this page the functionality reservations can be activated. The circled definitions navigate the working of the reservation.

Button “Use Forecast”

- Activated, the functionality forecast can be applied, forecasts on purchase and sales side can be made. When making a reservation's these become visible on the forecast(s) made.
- Deactivated, the forecast reservation is not applied and therefore the reservation will only verify the available quantities. The reservation columns and reservation option are removed from the forecast overview. The Forecast-functionality will give an error:

Segment Card Setup

Per segment it can be decided whether reservations are used. The reservation functionality can be set on the Segment Card.

Use Reservation

- Activated, users are able to make reservations in Agrio in this segment.
- Deactivated, users are not able to make manual reservations and even the reservation functionality is removed from the forecast and contract pages.

Agrio permissions

A default setup for the company can be setup and even on user level. This means that when a user is not defined in this overview, the settings of the “company” will be applied.

The type can be filled in and you can select subsequently the right reservation code that should apply. There are 3 options:

- Reservation of source group
- Not set
- Obligated
- Not Obligated

The definition of the options is as follows:

- Not set = Not able to make use of reservations.
- Obligated = Only the actual quantity that is reserved can be selected by a user.
- Not Obligated = The reserved and remaining available quantity of a lot can be selected.

In other words, certain users can have more rights. The most important difference is that a user with the option “obligated” depends on the reservation that is made during the forecast. When no reservation has been made on that level, then the user cannot select a lot to make a reservation from the sales contract or partial delivery, even when stock (a lot) is available.

That option can be applied to make sure that the user can only make a reservation within the defined forecasted quantities.

Example

When a forecast reservation of 100.000KG is made from NL (vendor) to RUSS (customer) for a specific variety and reservation size (35-55), then Agrio will allow the user only to make a reservation till 100.000KG. Even when the demand of the customer is 200.000KG.

However, when the option “Not Obligated” is assigned to a specific user. Then Agrio will check the forecast reservations but even the availability of the other stock (lots). Then the user can decide what to reserve, so he can fulfill the total demand of 200.00KG by reserving different lots aside from the forecast, because the setting “Not Obligated” has no restrictions.

Target & Source Groups Setup

The season starts with a general purchasing and sales forecast. In AGRIO Software forecasts can be entered per ‘target group’, for example a sales country on the sales side.

For the purchase side ‘source groups’ can be entered, for example a purchase region or a purchase country. By using ‘target’ and ‘source’ groups demand and supply can properly be matched. If the forecast for purchase and sales is known, then we know what expected quantities of potatoes we have available in which source group, and what quantities we expect to sell to what target group(s). Based on this information we can create reservations from source to target group.

Target Group(s)

To ensure that the forecast functionality works properly it is important that the ‘Target Groups’ are set on the “Customer Card(s)’. On the customer card a target group can be assigned to the customer. To change or setup more ‘target groups’ the user can use the option ‘select from full list’ (1) and then change or add another ‘target group’(2).

Source Group(s)

Not only for the Sales side forecasts can be made, also for the purchase side forecast can be set up. Therefore it is important to assign the right 'source group' to the vendor. The 'source group' of vendor 'Landbouwbedrijf van Doorn' is NL.

An example of using "Source Groups" & "Target Groups"

"We would like to reserve 200.000KG of variety AGRIA from our Dutch growers for customers in Russia".

If we want to do that we create a Sales Forecast.

1: On the forecast line(s) the target group can be assigned, in this example Russia (RU).

Then we select "reservations" (2) under the header "Manage".

In the new field that is opened(3), here we can go to "select lot" (4)

Another field is opened where we can select the lot that will be used for the reservations. When we have selected the right lot, click “ok” (5).

Now we see that the right lot is selected. We have to fill in the quantity we want to reserve of the lot we have selected (6). Now we see the reservation of 200.000KG is made for the target group Russia from the Source Group NL. When we close this screen we return to the Sales forecast made.

On the Sales Forecast we see the reservation made of 200.000KG for the target group Russia.

Forecast Sizes Setup

For each harvest year, based on the combination of the sector and segment, reservations sizes should be defined for all and/or specific varieties to make use of reservations. This can be set in the Harvest Year Setup under the heading “forecast sizes”.

Normally there exists a lot of different sizes which can be sold or purchased. At the reservation module these 5mm sizes can be covered by the reservation’s sizes, like “Normal.

1. Variety Code: When you leave this empty, the reservations will apply to all varieties. However, it is possible to define it for each variety. In that case, for each variety a row needs to be defined.
2. In this overview the related reservations sizes can be defined for the row that is selected in the first scheme (1). At this page it is possible to create new reservation sizes.
3. At those 2 columns you'll define the low and high value for the selected reservation size.
4. When modifying the setup the status is on "open", when the correct sizes are entered the status has to be set to "released"

Forecast(s)

In AGRIO Software, the term forecast is used to indicate what quantity is expected to be available (purchase) or requested (sale) in the harvest year to which the forecast refers. Multiple versions of a forecast can be entered for a harvest year.

The functionality forecast can be used to make a rough estimation of what can be expected for the upcoming year and can already make some reservations to make sure certain forecast groups will receive their goods. Forecast quantities are then compared to actual contract quantities from this year and last year. It is possible to make multiple forecasts, however there is always one leading.

Purchase Forecast

A Purchase forecast can be made to indicate what quantity is expected to be available in the harvest year to which the forecast refers.

When creating the purchase forecast, you can define what variables should be included and which not. The user can choose from:

- Target group
- Article (Variety)
- Cultivation method (Bio / Conventional)
- Class / Size / Quality
- Delivery period (Autumn / Spring)

In this way it can be determined whether one of these variables should be included in the forecast or not. Based on the settings the forecast overview will be built in Agrio. The different columns specify the variables used for the forecast;

1: When performing the “update forecast lines” the forecast of the current sector/segment/harvest years will be (re)calculated based on the

sector/segment/harvest year of the year that is entered.

2:

- Source Group; a specific group (can be a region/country/market) for which the forecast is made. Suppliers can be assigned to ‘source groups’ in the forecast. For example, a forecast for several suppliers can be bundled, for instance all suppliers from France fall into one source group and the expected available quantity is entered as one number in the forecast “From France we expect a quantity of 3,000,000 kilos from Lady Claire 00/99”.
- Item Number; for what item is the forecast made, in this case it is Lady Claire.
- Cultivations method: specifies for what cultivation method the forecast is made, multiple forecast line can be made. Where one forecast line includes for example ‘AGRIA SEED’ cultivation method ‘BIO’ and another line includes ‘AGRIA SEED’ cultivation method ‘regular’.
- Class Code: does the forecast include all the classes mixed up or is it for one specific class e.g. PB1
- Forecast size: are the sizes specified in this forecast for instance 35/55 or is the forecast made for field crop 00/99.
- Quality code: possible to specify the quality in the forecast.
- Quantity previous year: based on the variables, the system calculates for each combination of variables what has been purchased in the previous harvest year.
- Forecast quantity: expectations can be entered for each combination.
- Order final: the orders that are currently in the system for purchasing.
- Reserved quantity: the amount that is already reserved for that specific combination.

3: Quantity: The quantity on the forecast lines can be edited manually. When editing the ‘forecast quantity’ manually a log can be consulted, by clicking the three dots **(1)** next to the quantity. Here the adjustments made to the forecast quantity are shown **(2)**.

Sales Forecast

The functionality of the Sales forecast works almost the same as the purchase forecast. The same variables can be applied, like vendors on the purchase side, also customers can be assigned to groups, so-called “target groups” on the sales side. A target group is normally a region/country or sales market.

Entered forecast quantities are compared with actual final contracts from this year and last year. Of course forecasts for the coming harvest years can already be entered and modified, but the forecast screen contains the information for one harvest year.

If the forecast for purchase and sales is known, then we know what expected quantities of potatoes we have available in which source group, and what quantities we expect to sell to which target group.

Based on this information we can create reservations from source to target group. “We would like to reserve 200 tons of variety AGRIA from our Dutch growers for customers in Russia”. During selling and shipping, AGRIO Software will take these reservations into consideration. Chapter 4 “reservations” will explain this functionality in more details.

Reservations in Agrio

The purpose of reservations is to establish a link at an early stage between available stock (still in the form of a forecast or already in the form of actually purchased lots) and the recorded sales demand (forecast or actual contracts) Within Agrio reservations can be defined at the:

- Forecast overview
- Sales contract
- Partial delivery

Thereby, reserved quantities can be consulted at the:

- Warehouse assignment
- Lot card

Reservation - Forecast

It is possible to define reservations at the forecast card when this is activated on the Segment Card. Select the row where you want to define a reservation and click on "reservations".

The following scheme is displayed. Here you can define the correct "Source group"(DE) and the "reserved quantity" (10.000).

When you close the scheme, the reservation will become visible in the prognose overview for the selected row:

Reservation - Sales Contract

It is possible to define reservations at the sales contract for each sales contract line. Keep in mind that the reservation from the sales contract apply to the complete lot in general. The specific reservation regarding the right size code and packaging code will be made at the partial delivery card.

Open a Sales contract and click on "Function" (1), then you can select reservations (2).

When you click on "reservations" the next page will appear:

Here you can click on “select lot”(4). Then the page with the available lots will open and the available lot are displayed and can be chosen for the sales contract line.

1. Available lots that can be selected
2. Possible to make the filter range wider or more specific

Reservation - Partial delivery

To continue with the partial delivery it is required to select a lot. Also here reservation can be made, what influence the possibility to select a (complete) lot for the partial delivery.

Click on “select lot” (1). Then the following page will pop up:

In this page the available stock will be displayed (2) based on the applied filter settings. It shows the lot available lot that is reserved for the sales contract (reservations on contract level) wherefore the partial delivery is made. It is possible to activate or deactivate multiple filter (3), which might result in less or multiple lots. If you select "show multiple lots"(4) the system also shows the lots that are reserved on the forecast made (reservations on forecast level), these reservations are made on a higher level (reservations on forecast level).

Thereby, it is possible to review the details of a selected lot under the header "Process" (6). The details of the selected lot will be displayed in a new screen. Here you see different details of the lot.

1: Demand: the quantity that is required for the partial delivery

2: Available Based on Lot: the total quantity of the lot and the reservations made on this lot

3: Available based on one lot inventory record; the quantity based on one lot inventory record

4: Available Based on Source Group: here the total supply of the source groups is shown, what is reserved from the source group for a specific the target group, what is reserved for other target groups, what is available within reservation of source group, what is reserved from source group for other, what is available from free stock source group.

5: Assignable: shows what is available for Lot Selection and the Maximum assignable quantity, in this overview 10.000 because this is what is requested.

6: Details per Inventory Size: Here the details per inventory size of the selected lot are shown, the screen below will become visible.

Reservation Insight- Warehouse Assignment

At this page it is possible to consult the availability for each warehouse based on reservations.

The column "Available based on the reservations"(1) is not calculated automatically. To calculate this click on the button "Calculate..avail..reservations"(2). Then the system will verify the reservations and the availability.

Reservation Insight - Lot Card

On the 'lot inventory list' the different lots are visible. Here you can see how much is 'reserved (planned)' and what the position of the lot is after reservation.

When opening the specific lot card of for example lot 'CP-IPT17-0017' on the overview we can see that the purchased quantity is divided over the 5mm sizes, based on a normal distribution. Within the reservation module Agrio will update the reserved quantity in the related lot card.

Thereby it is important to know that the displayed lot inventory size overview (2) is related to the row that is selected at the lot inventory (1).

Making reservations on different levels

The chapters above explained the different settings, setup and instructions on how to create a forecast and/or a reservation and where this can be done. Important to know is the link between the different levels and reservations. For example, what if a reservation on a purchase contract is made for a specific customer? Can I then still reserve it for another customer?

The graph below shows the interlinkage between the forecasts and the different reservations that can be made. It also shows that reservations can be made for Target Groups, Customers or for Sales Orders/Contracts.

As shown in the graph there are in total 6 different lines, each line is a different reservation. The main purpose of reservation functionality is to make a connection/link between the available quantity/stock and the determined sales demand. Furthermore, with making reservations it becomes clear what is still available for sales and what is already reserved and is not available anymore.

If for example on a Sales Contract of a Dutch customer a reservation is made on a Lot from a German grower, this quantity is not available for other sales contracts to reserve.

The systems shows the maximum quantity to reserve per lot. So if for example 60% of a lot is already reserved for a specific customer. Only the other 40% of that lot can be reserved for other customer(s).

To explain the different reservations and the linkages between them, an example has been worked out. This makes it easier to understand the functionality.

Purchase Forecast

A purchase forecast for the year 2021 is made. The following quantities of different varieties and source groups are forecasted.

- 500.000KG field crop of Barcelona Seed from Germany (Source group DE)
- 300.000KG field crop of Agria Seed from the Netherlands (Source group NL)
- 400.000KG field crop of Bergerac Seed from Russia (Source group RU)

Sales Forecast

For the year 2021 also a Sales forecast is made. The following quantities of different varieties for the different target groups are forecasted.

- 200.000KG of Agria seed for Germany (Target group DE)
- 100.000KG of Agria seed for The Netherlands (Target group NL)
- 400.000KG of Bergerac seed for The Netherlands (Target group NL)

- 400.000KG of Barcelona seed for The Netherlands (Target group NL)

- 100.000KG of Barcelona seed for Russia (Target group RU)

Customers

In this example the following growers are used:

- Potato Trading Company & Co., target group NL
- Hinrich Kartoffelbetrieb, source group DE
- Sverdlovsk Kartoffelen, source group RU

In this example the following customers are used:

- Müller Agrarhandel, target group DE
- Jumbo Supermarkten, target group NL
- Bioland Agri Business, source group NL
- Schrieder Potatoes, target group DE
- Special German Potatoes, target group DE
- Igor Potatoes, target group RU
- Landbouwbedrijf van Doorn, target group NL

Reservation; *Source group to Target group*

A reservation on the purchase forecast for the sales forecast is a reservation on the highest level. Here the source group (purchase side) and the target group (sales side) are used. A reservation of 400.000KG (1) BARCELONA SEED is made on the Source group DE (2) (purchase forecast) for the Target group NL (3) (Sales Forecast).

On the Purchase Forecast (4) the reserved quantity of 400.000KG BARCELONA SEED on the Source group DE is now visible (5).

The reserved quantity becomes visible on the Sales Forecast (6). Here you can see that for the Target group NL a Sales forecast of 400.000KG BARCELONA SEED is made (7). The reservation that is made on the Purchase Forecast, becomes visible on the Sales forecast (8). Coincidentally in this example the forecasted sales quantity and the reserved quantity on the purchase forecast match each other. This means that you have reserved the complete quantity Barcelona Seed that you expect to sell in 2021.

Reservation; *Source group to Customer*

Now on the Purchase Forecast a reservation of 120.000KG (1) AGRIO SEED for customer (2) “Müller Agrarhandel” is made.

The reservation made becomes visible on the Purchase Forecast (3).

The reservation is also visible on the Sales Forecast. The reservation is made for Müller Agrarhandel. Because Müller Agrarhandel falls in the Target group “DE” this is also shown on the Sales Forecast (5).

Above, a reservation of AGRIO SEED 120.000KG of Source group NL for Müller Agrarhandel was made. It is also possible to make an reservation on a Source group for another customer. An additional reservation of 50.000KG AGRIO SEED (5) is made for

Schrieder Potatoes (6) is made. The total reservation of AGRIO SEED on the Source group NL is now 170.000KG, as you can see the total is summed up, when we click on the reservations, we see for what customers the reservations are made (7).

Different reservations have been made on the source groups. Reservations have been made for the target group “NL”(400.000kg) and for customer “Müller Agrarhandel”.

Reservation; *Purchase Contract Line to Customer*

Now, different Purchase contracts and Sales contracts can be created. In the example below a Sales contract is made for Landbouwbedrijf van Doorn for 200.000KG Barcelona SEED. Besides that, a purchase contract is made for Hinrichs Kartoffelbetrieb for 300.000KG Barcelona SEED.

To secure that the customer “Landbouwbedrijf van Doorn” receives their required potatoes a reservation is made on the Purchase Contract of Hinrichs Kartoffelbetrieb for “Landbouwbedrijf van Doorn”. This is a reservation made for a customer, therefore a Sales Contract is not required. This means that reservations can be made for all different customers without having a Sales Contract .

A reservation of 200.000KG is made from Hinrichs Kartoffelbetrieb (1). These potatoes are reserved for Landbouwbedrijf van Doorn (2). Here you see that this is a reservation for a Customer (3).

Now we go to the purchase forecast overview and see that in total 400.000KG is reserved.

If we look at the different reservations made we see a reservation from a source group to a target group (reservation on highest level) and we see a reservation made on a lot (purchase contract) for a specific customer “Hinrichs Kartoffelbetrieb”. Important here to see is that the total sum of reservations is not 600.000KG but 400.000KG. This is because the system sees that in the beginning a reservation of 400.000KG from Source group DE to Target group NL is made (reservation on the highest level). If a reservation is then made for a customer in de target group NL, the system deducts the quantity of the reservation for the customer from the reservations that where made from the Source group DE for the Target group NL. This to prevent double reservations.

Reservation; *Purchase Contract Line to Sales Contract line*

If we want to make a reservation on a Purchase Contract Line for a Sales Contract line we have to select the lot that will be used for the reservation. We have to see what quantity is available of that lot for reservation. In this example a reservation is made for the Sales Contract Line of Jumbo Supermarkten with a quantity of 125.000KG . We open the Sales Contract of Jumbo Supermarkten and make a reservation. There we have to choose the right lot that is used for the reservation when clicking on “select lot”.

When we select the right lot (1), we can also see what reservations are already made and we can see that the maximum assignable quantity is 100.000 KG. This is the result of the previously made reservations (2). A reservation from Source group DE to Target group NL of 400.000KG is made (3), however this reservation on the highest level can be overruled by a reservation on a lower level, because the reservation for the target group is made for target group NL. This customer also falls in the target group NL. Furthermore, a reservation on the purchase contract of Hinrich Kartoffelbetrieb for the customer “Landbouwbedrijf van Doorn” of 200.000KG is made (4). We now want to

make a reservation of 125.000KG for the specific Sales line of Jumbo Supermarkten. However the maximum assignable quantity is 100.000KG because of the previously made reservations for Landbouwbedrijf van Doorn. We will now make a reservation of 100.000KG for the Sales Contract line of Jumbo Supermarkten. However, their demand is 125.000KG on that Sales Contract line. This is also visible on the Sales Contract of Jumbo Supermarkten (5). So for the open 25.000KG on the Sales Contract line of Jumbo Supermarkten another reservation has to be made on another available lot.

On the total overview of the Sales Forecast we see that the “orders final” are 325.000KG (6). These are the sales contracts of Landbouwbedrijf van Doorn (200.000KG) and Jumbo Supermarkten (125.000KG) together. We also see that in total 400.000 (7) is reserved, this is because in the beginning we have made a reservation of 400.000KG from source group DE for target group NL of Barcelona Seed.

The reserved quantity is more than the ordered quantity, so we can think that we can already fulfill the complete demand of 325.000KG with the reservations made. However, the reservations made of Barcelona Seed are done from Source group DE to Target group NL. This means that we have made a reservation in advance of Barcelona Seed on the Source group DE for the Target group NL. However, these quantities are not all available already. As we have seen earlier above, we are 25.000KG short for the demand of Jumbo Supermarkten. Therefore, we have to zoom in on the reservations made.

If we now open the reservations on the Sales Forecast, we see that three different reservations are made on three different levels. 8; Target Group, 9; Customer, 10; Sales Contract Line

When we look at the reservation of 100.000KG made for Jumbo Supermarkten, we see on the right that the Outstanding Sales Quantity is 125.000KG (11) and that Reserved Quantity Forecast Size is 100.000KG (12). So we see that we are short of 25.000KG for that Sales Contract line.

Selecting a lot on which reservations have already been made for a Partial Delivery

Now we make another Sales Contract for Bioland Agri Business, for 180.000KG Barcelona Seed and if we then want to make a partial delivery of 35.000KG for Bioland Agri Business. On the Partial delivery created we get the Sales lines of Bioland Agri Business and assign the 35.000KG to that partial delivery. Then we want to select a lot for this partial delivery. However the system shows that no lots are available/visible as can be seen in the graph below.

The lot of Hinrich Kartoffelbetrieb is not visible for this partial delivery due to the fact that this lot is completely reserved for another Sales contract line of Landbouwbedrijf van Doorn and Jumbo Supermarkten. If for example due to modification to the contract of Landbouwbedrijf van Doorn, their ordered quantity Barcelona Seed becomes 180.000KG instead of the previous 200.000KG. We adjust the reservation made for Landbouwbedrijf van Doorn also to 180.000KG (1), the quantity was 200.000KG.

Now we go back to our partial delivery for Bioland Agri Business, we try to select a lot and we see that we now can select the lot of Hinrich Kartoffelbetrieb. We see that we can assign a maximum of 20.000KG (3) of the lot of Hinrich Kartoffelbetrieb for this partial delivery with a demand of 35.000KG (2). This is because different reservations are already made on this total. The total lot contains 300.000KG, however, a reservation is made for a Target group 400.000 (4) but this one we can overrule. However, there are

also reservations made on a lower level, namely for the customer Landbouwbedrijf van Doorn 180.000KG (5) and for the Sales Contract line of Jumbo Supermarkten 100.000KG (6). So only 20.000kg is left of this lot, for the partial delivery of Bioland Agri Business. You see all the "Open Stocks" available (7). If now the lot is selected for this Partial delivery, the reservation priority will change to Lot -> Sales. So we know that it is reserved for a Sales line.

Prepayments

Last modified: 2023-01-26

Introduction

If a customer enters into a sales contract with a trader, it may be that payment must first be made in advance. In AGRIO Software it is also possible to make advance payments on the contract. This document explains how prepayments in AGRIO Software work.

Sales Prepayment

Set Restrictions

Agrio Permissions can set whether restrictions apply when using sales prepayments. In the example below, a Confirmation is set up for the *Company* to be requested before being able to release a partial delivery for the customers to which unpaid prepayments apply. Different restrictions can be set per user. If not set, the restriction applies to the Company. Restrictions also apply to the mailing of logistics documents.

Figure 1 AGRIO Authorizations for release of partial deliveries after advance payments

- Not setup; For users, the restriction applies at company level. If this restriction is also 'not set', no restrictions apply.
- Disabled; Restrictions *deliberately* do not apply.
- Confirm; The user is asked for confirmation before being able to continue with the logistics process.
- Notification; Only a notification is displayed in the logistics process.
- Error; Users cannot proceed with loading until the customer has paid in advance.

With the check mark *Partial delivery approval of delivery* can be set that the restriction can be overridden by a set user. There will then be a button on the partial delivery with *Allow delivery*. If a delivery is allowed, the approver and the date/time on which the partial delivery release is allowed is recorded.

Usage

Sales Contract

To use prepayments, we need a sales contract. From the sales contract we can create a further payment.

Figure 2 Sales contract

Prepayment page

In the prepayment screen there are several options. Using the Percentage over quantities and *Percentage over amount fields*, a prepayment invoice can be created in different ways.

Figure 3 Prepayment screen

When creating the prepayment invoices, price adjustments are also included. For price adjustments that use scales with a *Date, Week or Month*, a *Graduated Date* can be specified on the prepayment screen. This is, for example, a (Delivery) date of a day of the week in which delivery takes place or the Month in which delivery takes place.

After setting up the prepayment, the prepayment batch can be created.

Figure 4 Release prepayment

Figure 5 Create prepayment batch

Figure 6 Navigate to Prepayment Batches

Prepayment batch

The prepayment batch looks the same as the regular invoice batch sale. The follow-up process is also the same. The numbers and amounts are checked in the batch and then an unposted invoice is created.

Figure 7 Prepayment batch

Sales Invoice (products) for Prepayment

The following sales invoice has arisen from the invoice batch. After this has been booked, partial deliveries, depending on the restrictions, can no longer be released before the customer has actually paid the payment and this payment has been processed in AGRIO Software.

Figure 8 Sales invoice (products)

Partial Deliveries

Depending on the restrictions and/or payments of the customer, we can go further in the logistics process. In the case below, a confirmation will be requested. Restrictions also take place when sending logistics documents by e-mail.

Figure 9 Restriction on Partial delivery when you want to release it

Delivery Invoice Batch

When the partial delivery is finished, a new invoice batch for deliveries is created.

Figure 10 Create new invoice batch for deliveries (picture still in Dutch)

The button above gives us a batch with the result below. An invoice batch on which the prepayment is deducted. The deducted may be removed from the invoice batch if desired. The deduct will then be reflected on the next delivery invoice.

Figure 11 Invoice batch deliveries (picture still in Dutch)

When a Delivery of the contract is invoiced, the system settles the prepayment on the Delivery Invoice. If it concerns a Partial delivery of the contract, the system will settle up to the amount of the total amount of the Delivery Invoice.

- E.g. Prepaid: 1500,- Total amount. Contract 4500,-
- Invoice delivery 1: 250,- Settled: 250,- (small partial delivery)
- Invoice delivery 2: 250,- Settled: 250,- (small partial delivery)
- Invoice delivery 3: 250,- Settled: 250,- (small partial delivery)
- Invoice delivery 4: 3750,- Settled: 750,- (full delivery open. tot.)

On the Partial delivery line, the Last delivery check box can be selected. If enabled, the system will settle the entire remaining amount of the prepayment when creating the Delivery Invoice. Depending on the outstanding amount, an Invoice or a Credit Note can be generated.

Sales Invoice deliveries – Prepayment deducted

The image below shows the unposted sales invoice for the delivery. In this invoice, the prepayment is deducted.

Sales Seed Material

Last modified: 2023-01-26

A sales contract can be marked as Is Sales Seed Material. This means that the contract is used for the sale of goods to growers for the next season. When marked, a new column may be used on the sales contract lines, called Sales seed – Hectare qty. This column can be used to invoice the grower a fee for the amount of hectares that is contracted.

Invoicing a fee per contracted Hectare

Figure 1 Sales contract

Attach a price correction to the sales contract line if a fee for sales seed hectares is needed. The price correction has a correction quantity of Sales seed:

Figure 2 Price correction HA-FEE

Once setup correctly, the price corrections can be invoiced separately from the regular delivery invoices by using the Sales seed batch:

Figure 3 Creating a Sales Seed batch

This results in the following invoice batch sales:

Figure 4 Invoice batch sales

Invoicing the Calculated Pool Price for Sales Seed

Sales seed material may be invoiced according to the calculated pool price. Therefore, a pool and a matrix for Sales Seed Material must be set up.

Sales Seed Material – Size percentages matrix

In order to be able to manipulate the percentual size distribution in the delivered sizes of sales seed material, we need a matrix with percentual divisions. In the example below, a division is created per size and source group.

- The percentages should add up to 100% and the matrix variable INVENTSIZE must be used.

Figure 5 Sales Seed Material - Size percentages matrix

Calculation in pool

As shown in the example below, 75.000kg is delivered as Sales Seed Material. A Total Amount is calculated based on the pool price of € 43,29.

Figure 6 Pool AGRIA_21

The delivered size is 3555mm. The quantity delivered for each 5mm size is calculated according to the matrix Sales Seed Material – Size percentages matrix. This is then calculated over the pool sizes set up in this company:

Figure 7 Quantity in pool sizes

If everything is configured correctly, a sales seed invoice may be created. This creates a sales invoice batch and may be invoiced eventually.

Lot Journals

Last modified: 2023-01-26

Introduction

This document explains the functionality of Lot Journals. With Lot Journals, you can alter the quantities of the lot inventory. You can alter the total quantity, but you may also change the quantities in the related sizes.

Lot Journal Setup

To be able to work with the Lot Journal, you need to setup the Lot Journal Template in the Segment Setup.

Figure 1 Segment Setup

Fill in a Code, the Sector Code, Segment Code and a No. Series.

Figure 2 Lot Journal Template

Lot Journal Usage

Now that the Lot Journal is setup, you can find and use it under 'Lot & Logistics'.

Figure 3 Lot & Logistics > Lot Journal

When opened, you may select the lot you want to alter.

Figure 4 Lot Journal > Lot Selection

A more convenient way of making corrections may be to navigate to the Lot Inventory and click 'Create Corrections' for the selected Lot Inventory record. A record in the Lot Journal will be created automatically.

Figure 5 Create Corrections via the Lot Inventory

Editing the Lot Journal

Once a record is created in the Lot Journal, you may alter the quantities. There are a couple of ways to alter the quantities.

Alter the difference

You may enter a number in the 'Difference' column, which will calculate the 'New Position' after the difference. The difference per size is calculated automatically accordingly.

Figure 6 Alter the Difference

Alter the New Position

You may alter the New Position to the value you want. The Difference and sizes are recalculated automatically.

Figure 7 Alter the New Position

Alter the position in sizes

You may also alter the position in sizes. In the example below, the position in 3540 is changed from 58kg to 33kg. Changes in sizes should add up to the total of the Lot Inventory. If the New Position and New Position Lines do not match, the line will turn red. Therefore, 25kg should be added up in a different Lot Journal Sizes line.

Instead of changing the New Position in the size lines, you may also alter the percentage on the Lot Journal Sizes lines.

Figure 8 Alter the position in sizes

Posting the Lot Journal

When the quantities are altered and verified, the Lot Journal is posted. When posted, the Lot Inventory is updated. Be careful, posting a Lot Journal cannot be undone.

Figure 9 Post the Lot Journal. This cannot be undone.

Position Snapshot

Last modified: 2023-07-26

The Position Snapshot is a module that enables Agrio Software users to create an 'image' of the position on a certain moment in time. This 'image' is called a snapshot in Agrio Software and it exports the entire position to snapshot tables.

Setup

User Permissions

Enable the snapshot module by granting a user access to the position snapshot.

Figure 1 Agrio Permissions

Job Queues

Setup a job queue to create a snapshot on a given interval. Use Codeunit 11270665 (Position Snapshot Mgt) to automatically create snapshots.

Figure 2 Job queue entry for automatically creating snapshots.

Usage

After a user is granted access to position snapshots, a new button appears in the General Setup for this user. When clicking this button, the snapshot screen opens.

Figure 3 General Setup

Figure 4 Position Snapshot

When clicking 'New', the user can create a new snapshot. Creating a snapshot exports data to snapshot tables. These tables are not accessible withing Agrio Software but are used in external tools. Therefore, Agrio Software contains queries which can export the snapshot data. The queries are added within the Business Central Web Services.

Web Services

In the table below, all snapshot tables are displayed. These queries are used to extract the snapshot data into external tools, such as Excel or Power BI.

Object Type	Object ID	Object Name
Query	11270663	PS - Agrio Forecast
Query	11270664	PS - Agrio Forecast Line
Query	11270665	Position Snapshot
Query	11270666	PS - Lot
Query	11270667	PS - Lot Inventory
Query	11270668	PS - Lot Entry
Query	11270669	PS - Lot Inventory Size

Preliminary Position

Last modified: 2023-01-31

Introduction

When a lot selection occurs on a transport or partial delivery, previously this lot was seized by placing an 'Automatic Reservation'. This functionality is outdated and we have phased it out with the introduction of the new 'Preliminary Position'. With this functionality, we hope to provide better insight into inventory and the performance of Agrio Software is improved. This document explains what preliminary position is and how to use it.

Preliminary Position

In Agrio Software, we knew the following statuses for position: actual and planned. The planned position is always one step ahead of the 'Actual' position. In this example we look at the position (preliminary), however this applies as well for the 'qty in stock (preliminary) column.

Example 1

In the example below, there is a purchase contract and a released processing order that consumes 30,000kg. Because the processing order is released, a planned position is created in graded sizes. Should the processing order be reported finished, the 'Actual' position of the purchase line is reduced from 90,000kg to 60,000kg. The 'Actual' position in sorted sizes is raised from 0 to 9.000kg, 15.000kg and 6.000kg, respectively.

Figure 1 Lot inventory planned and actual position (with released process order)

Added to these two positions is now a third, the Position (preliminary). The preliminary position goes one step further than the planned position. Whereas the planned position looks at released orders (think of processing orders, partial deliveries and transports), the preliminary position looks at open orders with selected consumption.

Example 2

In the example below, the same purchase contract and process order exist as in Example 1, however, the process order is not released but open. We see that the preliminary position has

been reduced by 30.000kg, while the planned position is still 90.000kg.

Figure 2 Process Order status Open

If you click on the 60,000kg, you can see where this number comes from. In this case from an

open processing order.

Figure 3 Lot entries

Now when the processing order is released, we see the same results as in Example 1. We also see that the preliminary position follows the planned position. This is because no open process orders exist for this lot.

Figure 4 Process order status released

When the processing order is reported ready, we can see that the preliminary, planned and

'Actual' position are aligned.

Figure 5 Processing order Status Finished

Tips

- The preliminary position may be negative. This makes it quick to see in the inventory overview whether too much of a lot inventory is planned or not
- Review the pages and review the sequence of the columns

Adjustments

The following pages feature the preliminary position:

- Lots
- Lot inventory
- Lot entries
- Variety statistics
- Partial delivery lot selection

Consumption & BOM's

Last modified: 2023-01-31

Introduction

In AGRIO Software, both sorting and packing / bagging are handled with process orders / production orders. Process orders can be used to handle the sorting and packaging of seed potatoes as well as the sorting and packaging of ware potatoes. Of course, both process orders with their own characteristics. This topic focuses on the ware process within AGRIO Software.

This has value when products are actually produced/packaged at a packaging station. Different segment settings can be applied to make sure that the process order is executed in the right way and that for example relevant packaging material is deducted automatically. In this topic all related subjects will be discussed. Think of segment settings, bill of material (BOM) at item card, deducting packaging material (FIFO) automatically based on packaging codes and producing/using multiple lots.

Process orders

For both Seed and Ware potatoes, on the process order the user:

- Selects the source lot(s) for that process order
- Specifies what products he/she would like to produce
- Specifies the packaging and possible other materials that are needed for the process order
- Sends the production order to the production employee or to the grower, depending on who does the actual production
- Record the used quantities of the source lot and the produced quantities on the 'production lines'
- Post the production order, after which the inventory levels are updated.

Thus, production orders can be created for growers (if the stock is still at the grower's location) and/or for our own production employees (if we are doing the production).

AGRIO Software supports different types of process orders:

1. A process order for Sorting potatoes: one lot (often 00/99) leads to three or more sorted sizes, e.g. 28/35, 35/55 and 55/99.

2. A process order for Bagging of seed potatoes. One already sorted size (e.g. 35/55) is bagged in jute or big-bags.
3. A combined process order, where one lot (often 00/99) is sorted and immediately (partially) packed.
4. A process order for the packaging of ware potatoes. In fact the same functionality as the packaging of seed potatoes, but here also foil, stickers, or other needed material is recorded in the process order.

AGRIO Software handles the packaging materials through the so-called "Item-Units-of-Measurement" table. For every item, we can define in what packaging this item can be delivered to our customer, e.g. 5Kg floury potatoes in 'Gold-Label' foil, in crates on pallets. Also the quantities of bags per crate and crates per pallets are defined in this Unit-of-Measure table.

Production orders for packed potatoes

Also for the production of packed potatoes the process orders in AGRIO Software will be used. A lot of functionality is present in AGRIO Software:

- Process orders can be created for own warehouses / packing stations. Lots are transported via a transport order first to our own location, then a process order can be created that will use these lot(s).
- Process orders already do have 'Usage' lines (which lot(s) will be used for this production order, and 'Production' lines (which products/lots will be created during production). These lines also include the packaging (pallets, crates, foil) on each line.
- Used lots are subtracted from the lot inventory in AGRIO Software. Produced lots are added to the lot inventory in AGRIO Software.
- Produced lots can be selected on partial deliveries for delivery to the customer(s).
- On a process order, an additional table will contain all needed materials from the Bill-Of-Materials (BOM).
- Packaging material can be deducted automatically by the use of "lots in use"
- If multiple potato lots are selected on a process order (e.g. 10.000 kilo of lot X and 5.000 kilo of lot Y), then AGRIO will create a new lot-number for the produced end-product.

Segment Settings

At the segment "processing" tab the following settings can be turned on to support the WARE process in AGRIO:

Split process orders in lot inventory

Required to activate when using "consumption".

Use consumption

With this setting it is possible to select multiple "usage" lots at the process order and in that scenario the production line will get a "new" lot number. Also a field "multiple lots on process order" will become visible at the partial delivery.

In that case only a "packaging" process order can be generated from the partial delivery.

When activated the field "components" will become visible at the process order.

Use BOM (Bill of Materials)

At the item card the BOM field becomes available. The BOM can be used to predefine the usage (potato), variable (water, packaging) and fixed items (labels).

Keep in mind to activate the following setting as well "packaging autom. to components"

Multiple lots on Process order

When activated it is possible to create a process order from the partial delivery without any lot selection. The process type must have type "merge". When this setting is deactivated the standard AGRIO flow will be handled, meaning lot selection is mandatory at the partial delivery before you can create a process order with process type "standard".

Lot Selection Process order

This field has two options: Default and Location. If set to Default, the Lot Selection on the Partial delivery work as now and all available lots can be selected. The option can also be placed on "location". When this field is set to Location, the Lot Selection of the process order will only display the stock that is present at the Location.

Packaging autom. to components

With this setting "packaging material" (e.g. Big bags, EP12) is taken over to the "component" list of the process order even without a linked BOM (item card), so it will be deducted when finishing the process order. When activated the field "components" will become visible at the process order.

With this setting "multiple lots on process order" is not activated. That means that the regular "seed" flow can be followed (select lot at partial delivery, create combination process order)

The packaging codes that are defined at the item unit of measure setup are leading, this will only be taken over to the component list if the packaging codes have a linked "BOM packaging item" which can be defined at the "units of measure" table.

Usage Fictional Lot Nos

With this option a column will become visible at the partial delivery. This can be selected and subsequently values can be defined to create the fictional lot no. Subsequently the process order can be generated, however the fictional lot must be replaced before finishing a process order and partial delivery.

Keep in mind to fill in the "Fictional Lot Nos" at the segment card:

Autom. Create fictional lot for consumption

When at the partial delivery no usage lot has been selected and the user wants to create a process order, the system will generate a fictional lot when creating the process order. Subsequently the fictional lot should be replaced by the actual lot (this is not yet fully supported).

Segment dependent setup

153 – Process order type

When selecting multiple lots as usage it is required to set the "handling" at "merge" for the "packaging order".

Always new lot for consumption

If this check box is checked, the system will always create a new lot no for a consumption processing Order for the Production Line (End Product). So the stock of the end product always comes to a new lot no and the consumed stock is debited from chosen lot(s).

The new number can be created in 2 ways:

No series can be defined at the segment card at tab "numbering" – field "process order lot nos". This setting is leading pertaining to the AGRIO setting.

Process Order Line No

Number will be generated based on the process order number + row number (e.g. CP-PROC22-0001/10000). Only when above field "Process order Lot Nos" is empty.

Agrio setup - Spatio Setup

Use production

This setting should be activated when using "lots in use", meaning that the first received packaging material/lots will be assigned and deducted automatically on the process order (FIFO).

BOM (Bill of Material)

A BOM can be defined at the item card and at the process order AGRIO will work with the predefined BOM.

Segment card

At the Segment map for Sector: POTATO and Segment: WARE the checkbox Use BOMs can be enabled. This means that the BOMs can only be created for items that fall in that Sector and Segment. This can be done by activating the setting "use BOM".

Item Card

On the Item card, the Prod. BOM No. present. Here a Production BOM No. must be completed. If no BOM is yet linked to an Item card, you can click on the AssistEdit (...) and the system will create a new BOM. The new Bill of Materials will have the same No. as the Item No.

If a BOM is already linked and the user clicks on the AssistEdit (...), the card of the latest BOM version will be opened.

In "Agrio Leidend" the Production Item MEXICANBABYPOTATO (Mexican spiced baby potatoes) has been added and will be used as example.

BOM

Below the Bill of Materials. The BOM is created for a Production Item and the Unit Code (FL500GR) is specified on this BOM. This means that the bill of materials is set up with numbers to be able to produce one foil packaging of 500 grams.

The raw materials can be added via the BOM lines. Using the Input unit (GREEN) you can indicate how much raw material is used and how much this is in the Base unit. These quantities are recalculated to 1 Base Unit (BLUE) of the item to be produced. These numbers are ultimately important for the Material Lines for a Process order.

Versions

At the BOM card multiple versions can be defined where the latest is leading and a BOM can have 3 statuses:

- Under development
- Open
- Certified

To set up a BOM like above is only possible when the specific item has 1 “item unit of measurement” code. Thus this item is always produced in the same way with the same materials.

Item units of measurements

However, in AGRIO it is possible to define multiple “units of measurements” codes from the item card. In this way the same item can be produced/delivered for example in different packaging codes. Customer A wants the product in boxes where customer B prefers it in crates. For each combination you cannot define a BOM.

Process Order

Via a Sales order, a customer orders 250 x Mexican seasoned potatoes in a 1000 Gram package, so 250 x FL1000GR, which corresponds to 250 KG. From a Partial Delivery, a

Processing Order is created with the production line below.

Note: The customer has ordered a different unit FL1000GR than with which the Bill of Materials is set up FL500GR and that the Bill of Materials and Material lines are calculated in such a way that the system can calculate the correct quantities for different packages.

Material Lines / Components

The BOM lines can have the following types:

- Usage; this is the "input" item that is required for producing this end product
- Variable; this can be foil, oil.
- Fixed; think of labels, stickers

Because a BOM is linked to the Item MEXICANBABYPOTATO, the BOM lines are copied to the Material lines at the Process Order. These can be accessed through the "components" button on the process order.

When you click on it, the calculated material lines will be displayed (when the process order has status released):

Explanation of the Material lines:

GREEN

These are Input quantities from the Bill of Materials copied to the Material lines. These are the input numbers to produce 1 foil package of 500 grams.

BLUE

These are the Base quantities from the Bill of Materials copied to the Material lines. These are the quantities to produce 1 Basic Unit (1 KG) of the Production Item.

PURPLE

This is the Output quantity (Base) filled with Quantity (Base) from the process order line. When the quantities on the process order line change, this column is automatically updated.

ORANGE

This is the calculated Consumption of the Material line. The result of PURPLE x BLUE, so Output (Base) times Number of Basis (Base).

Process Order

It can be that the usage lot is selected at the partial delivery. When then the process order is created the usage lot will be copied. Nevertheless, it can also be the case that you don't know the usage lot upfront but during production. Therefore it is possible to create the process order from the partial delivery even when no lot has been selected. The lot selection is then still needed at the process order.

When the usage quantity is insufficient then another row will be added when a new lot number is selected. When this is the case the user has to fill in the right usage quantities for each line. It is also possible to "replace" a selected usage lot.

New Lot Number

Partial delivery generated and the usage lot (CP-INP21-0005) has been selected. When creating the process order then following information is taken over:

When another usage line is selected:

Manual Process Order

For consumption is it possible to create a manual process order to produce goods upfront. At the process order an "end product" can be selected with all relevant information like "size", "class", "quantity" etc. This button will become visible when the process order type has type "merge" (see chapter segment settings).

Field that can be entered. For the input unit of measure, click on the three dots (...)

When a BOM is related to the end product then the “usage” item line will be taken over and the system can calculate with a waste %. This works as well when no BOM is

defined, then the user has to select the right lot (item).

SPATIO

In this section planboard related information can be defined when plants will use the planboard and workplaces at the floor. The “lots in use” section can be activated at this section. This section will be extended in the future when more plants will use this.

Setup

SPATIO Setup

Activate “use consumption”

Spatio Master Data

Define the machines, resources and mapping-resource workplaces. This will come back at the process orders. Some activities in the background are needed as well to activate this in the right way.

Lots in Use

The lots that are put into use for a machine are now mandatory set per location. When a company has several locations and each location has its own processing orders, each location can set itself which parties are in use.

When lots in use are set via segment – lot in use, the new location column must be filled in (even if you only have one location) and only then can you execute “Select lot”. When the function “Select lot” is executed, the system also only shows Lot (stock) that has been moved to the location via a transport order, i.e. Lev-Loc. In short: You can only start using lots that are also at the location.

Nevertheless, the system can do automatically as well. Click on “get items” and fill in the values that should be applied. AGRIO will check if there is inventory and based on the FIFO method the right lot(s) will be added according to the defined filters.

The workplace and machine are no longer mandatory for lots in use. This means that if a workplace (e.g. KP1-A) is entered on the process order the system will first check if that combination exists in the “Lots in use” table. If not, then it will check which lot is in use for that item no and location.

Lots in Use – Process Order

When the packaging process order has been released the “component” lines will become available. In this overview it is possible to assign manually the right lot to a packaging item or to apply the “lots in use” functionality upfront. Then the user has an idea of which lots are selected. However, the right lot will be assigned automatically when you finish the process order. When AGRIO notices that there is no stock available a notification will pop up.

When finishing the process order the quantities of the “packaging” stock are deducted, because it cannot be used anymore for other process orders.

If 1000MTR is required for a process order and only 600MTR is in use then AGRIO will split the line (600 and 400). The lots in use functionality will check if another lot is in stock as well and will assign it directly based on the FIFO method. Meaning the first assigned lot is closed and a new lot no will be in "use".

Reverse

Finished a process order with 10 x JUTE25. The assigned lot is deducted from the inventory (100 at inventory – 10 usage = 90 left at location X)

- When you reopen the process order (status = open), the assigned lot will be reversed (lot inventory = 100). When you finish the process order again, the system checks the available lots and will assign the lot that is in use at that moment.
- When you change the status from finished to released, then the system will "reserve" the 10 that was already deducted from the inventory. This means that the available inventory remains 90 at location X.
- If you change the quantities and/or packaging material; for example, 12 * JUTE25 should be deducted instead of 10. The system will then validate which packaging lot is in use and will assign the right lot to the extra 2 JUTE25.
- The assigned lot that was used for deducting the 10 JUTE25 remains the same, but now also the extra 2 are deducted.
- If the packaging material should be 6 instead of 10, then the system will correct the assigned lot where 4 JUTE25 will be added again to the inventory. Only the 6 will be deducted from the inventory (reserved lot).

Fictional Lot

At the partial delivery a fictional lot can be generated manually or automatically, depending on the segment setting. When a BOM is linked to the produced item then a fictional lot will be created for the usage item (BOM). Later in the process the fictional lot should be replaced by the actual lot.

Select this field result in the following sub page.

After clicking on OK the fictional lot is created and visible on the usage line

See for more information the topic about "fictional lot no".

Handling methods

Introduction

This topic was written because it is possible to make a processing order in different ways, namely:

- Standard
- Merge
- Parallel

The following explains how the different options are used.

This can be set up by going to sector settings, then segment dependent setup. Search for Process Order Type. You will then see the overview below:

A process order cannot have different handling methods at the same time. So multiple processing order types will have to be created.

A sorting order with standard AND a sorting order with merge, for example.

Different ways of handling

1.) Standard

The default option is the standard setting. Here, the process order uses the lot1 to 1. That is, the selected batch is used for production. This does not affect the number of production lines, but for all production lines, the same usage rule is used. The

screenshot below shows that the same lot is used.

2.) Merge

Merging can be used, for example, at the end of the season. If several lots still exist with small leftovers, this can be merged into a new lot. An example:

Usage lines: Lot A with 100kg, Lot B with 150kg and Lot C with 250kg. This results in a production line: Lot D with 500kg.

3.) Parallel

Parallel can be used when you want to handle multiple lots at the same time. For example, in the usage lines, you use lot A and B. Then, in the production lines, lot A and B are also used.

Lot A will assign its stock to the production lines of lot A. Lot B will do the same, but for lot B.

Partially Reporting Back

Last modified: 2023-01-26

Partially Reporting Back & Deliver

In some cases, the grower does not sort his field crop in one go. The grower reports back his quantities each time he has sorted, until the lot sorting process has finished. The sorted quantities may already be delivered until the full lot has been sorted. Moreover, the sooner the grower reports back his quantities, the more storage premiums the grower will receive. This document explains how reporting back in multiple times is supported.

Example

A grower gets an order to sort the total of his field crop in different sizes. The lot is too big to be sorted at once. Therefore, the grower sorts in three times. In the example below, the grower reports back 75.000kg of 3555mm whereas 100.000kg was estimated. The grower indicates he has not finished sorting. The 75.000kg may already be packed and delivered. The estimated 25.000kg may also be packed and delivered already. This may be useful since the 75.000kg may have been put into the shed and the 25.000kg can be loaded onto a truck directly from the sorting machine.

The grower may receive extra premiums over the 75.000kg, because he needs to store them for a longer time. Moreover, the AGRIO Software user has a very up-to-date insight into the stock in AGRIO Software.

Figure 1 Partially Reporting Back (75.000kg of 100.000kg)

Setup

In the Segment-dependent setup, master data no. 153 (Process Order Type), the Process Order Types are defined. For each Process Order Type, one can define if partially reporting back is enabled or not. In the example below, partially reporting back is enabled for the type 'Grading'.

Figure 2 Segment-dependent setup, master data no. 153 (Process Order Type)

Usage

Process Order

Feedback from the grower about his sorted quantities is registered on the Process Order. A user may enter the feedback manually by clicking the 'Report Back' button on the Process Order production lines. The feedback is registered for each size individually. Once all the feedback is entered, an overview can be found under the button 'Feedback Reports'.

Figure 3 Process Order feedback buttons

Both on the 'Report Back' button as well as the 'Feedback Reports' button, the feedback needs to be approved by a user. In the example below, four lines have been reported back of which two have been approved already. We can also see that three of the four lines have the indication that it is the 'Last Feedback'. This means that AGRIO Software will replace the lines on the Process Order production lines with the feedback, because it is complete. If it is not complete, like the third line, AGRIO Software will create a new line in the Process Order production lines. This new line results in a new line in the lot inventory list.

Figure 4 Partially reported back lines

If feedback is created but not approved yet, a number will be shown on the Role Center. This indicates that open feedbacks are present.

Figure 5 Role Center open feedbacks

Reporting back through the growerportal

If a Grower portal is attached to the AGRIO Software environment, growers may report back their quantities in multiple times through the portal. If they do so, the feedback will be processed to AGRIO Software and will result in automatically created feedback lines in the Process Order. The user does not need to create the feedback lines, he only has to approve them.

Follow-up from the Sorting Order

Partially report feedback is registered as a new line in the lot inventory in AGRIO Software. This means that either the newly created stock or the 'To be processed' stock may be selected on a following Packaging Order, Partial Delivery or Transport Order.

In the example below, two lines are visible on the Lot Selection screen from the Partial Delivery. The 208.602kg is stock that is not reported back yet. The 50.000kg is reported back. Both may be used in following orders.

- Though not reported back quantities may be selected for packaging, delivery and invoicing, an error will be shown whenever a grower tries to report back less than that there is already on following orders.
- Example: 208.602kg was not reported back yet. 200.000kg is put on following packaging orders and delivery orders. The grower reports back 190.000kg. This results in an error saying that there is 10.000kg too less.

Figure 6 Partial Delivery Lot Selection

Single Report Back

Though it is possible to report back in multiple times, it is still possible to report back in one go. One may just edit the quantities on the Process Order production lines if no feedback reports are present on that line.

Using quality points on samples

Last modified: 2025-07-24

Introduction

In Agrio it is possible to enrich a sample with quality information, using the quality lines. This topic document describes the functionality of using entered price corrections on the related purchase line when the lot is being subject to a sample. This can lead to a bonus/ penalty price correction line on a (final) purchase invoice

Reading this document requires basic knowledge of the following topics:

- Price corrections
- Quality sampling
- Price lists

The purpose of this functionality is to enable the end user to apply penalties/ discounts on the purchased lot, depending on the quality of the lot.

For instance: a 'bad lot' (a lot of damaged goods/ high disease) can lead to a price correction being added to the purchase line, involving a penalty (negative amount) per x quantity, resulting in a lower price per x quantity for the grower.

The above means that both the grower and the buyer should be clear about the 'game rules': measurement is transparent and scoring/ conditions about possible penalties/ bonuses is set upfront.

Settings

In order to make use of this functionality, some set-up has to be done:

- Create a price list for each score what should have impact on the price
- Create a price correction for each of the above price lists

- Edit the related sample settings

Create a price list

In this document, an example of a penalty system for damaged goods will be used. In this case, we have the following scoring table:

the above stated amounts are penalties per 100KG goods

item 'cartwheel' is exempt from the above penalty system (because it is not there).

scoring multiplier

light damage: 1

medium damage: 3

heavy damage: 5

When inspecting the goods, the inspector can classify a 'damage severity' to a damage point: light, medium or heavy, all having a different impact on the total of damage.

Starting with creating a price list, open [Setup, Price lists] and create a new price lists. In this example, 'Variety' is being used as the distinctive characteristic:

This price list is called 'QUAL_DAM'. We will use this price list in the next step, the price correction.

Create a price correction

Now the price list has been created, the price correction(s) can be created. Via [System, Price corrections] create a new one, make sure the 'correction type' is set to 'Price list':

Link the just created price list in the 'Price list No.' field, make sure the 'Price Uom' is set-up correctly as well. (in this example, the '100KG' code is being used, because the penalties will be applied per 100KG).

Make sure all other fields are filled the way that fits your needs:

1. Module: Where to use this price correction?
2. Calculation method: How should this price correction be handled?
3. Billing time: at what point in time should this price correction be added tot he invoice?
4. Price List No.: To which price list should this price correction look in order to make the necessary calculation?
5. Sample Type: based on the latest released, leading sample type should the calculation be made?
6. Price UOM: possibly, a penalty/ bonus will be applied based on a calculation of this price correction. In this example, the penalty/bonus will be applied per Tonne
7. Correction Quantity: Over which quantity should the applied bonus/ penalty be calculated?
8. Print on Contract/ invoice: should this price correction be visible on what document?
9. What should the description be?

Edit the related sample settings.

Finally, the quality characteristics lines have to be linked tot he just created price correction. This link will enable the system to check if a price correction can be applied on the purchase line.

Open the relevant sample (box/ test dig/ etc...) of the right harvest year via [System, Sector, Segment, Harvest year setup, Quality characteristics]:

In this example, a box-valuation has been created which can be used on lots, with the following setup:

The example setup above shows:

- 4 lines:
- 3 for reporting (to be filled in by the inspector), saving light/ medium/ heavy damage with the weighting factor
- 1 for displaying the total damage, which is a 'Total'.
- The max. value for the 'total' line is 100: this is also the max. value where our price list will look at.
- The 'total' line is the SUM of the 3 reporting lines (because of the 'Quality group code' field).
- the created price correction is linked to the 'total' line. The end value from this line will be compared with the price list lines.

When the sample definition is released, it will be used when creating a new sample.

Please note: when having only one characteristic to be calculated, make sure that line still has the value 'Total' in the 'Totals' field. Only lines with the 'Total' value will be evaluated.

Quality characteristics: usage

Add price corrections on purchase contract lines

In order to use the quality points for applying bonus/ penalties on goods, the related price corrections have to be added to the purchase contract line. By doing this, Agrio knows to calculate with these lines.

Add the price corrections manually/ by selecting a contract type:

Visible is:

- 3 price correction lines
- Invoicing time: on 'Final invoice' (because this is defined on the price correction)

Entering a sample

When a sample is created for a lot, which has the quality characteristics set-up, the following sample for the 'ANDROMEDA' variety can be created:

In this sample, the 'DAMAGE' line (the 'Total' line, as the previous sample setup showed) is leading for calculation. The sum of the light, medium and heavy damage is $((7 * 1) + (2 * 3) + (2 * 5)) = 23$.

When this sample is 'Leading' and 'Released', the sample will be leading for calculating quality points.

Creating the invoice

In this example. 24.000 KG has been transported & invoiced, resulting in the following purchase batch invoice lines:

This example explained:

- 24.000 KG transported.
- Prince correction is taken per 100KG, so 240 times.
- The 'score' of the damage was 23. Looking in the prince lists 'QUAL_DAM' for variety 'Andromeda', this score evaluates in the line between score '21' and '50': €-0,15.
- $240 * €-0,15 = €-36,-$
- The relevant price correction code will be added as well.

Tips & troubleshooting

When working with the quality measurements for price corrections, set-up is vital. If price correction(s) are not applied in the invoice batch lines, check the following:

- On the Price correction:
 - Module correct ('purchase')?
 - Calculation method ('Separate on invoice', else no extra line visible)
 - Billing time
 - Sample type
 - Price list linked
 - Print on invoice = 'True'?
- On the linked price list:
 - Correct lines available with correct columns? (harvest year, variety, points from & to)
- On the quality lines setup page:
 - Totals column filled with the value of 'Total'
 - 'Display as': 'Points'?
 - Weighting yield with value >0?
 - Price correction code field entered for 'Total' line?
- On the purchase contract line:
 - Price correction available?
 - Sample type correct?
 - Billing time
- On the sample:
 - Quality points calculated?
 - Released
 - 'Is leading' checked on.

When using multiple quality checks, it is useful to add the price corrections to a contract type code, such as in the example below:

The full quality check means (in this example): checks on Rhizoctonia, damage & scab.

Create Partial Deliveries

Last modified: 2023-01-31

Introduction

Within Agrio we know partial deliveries, with partial deliveries demand can be linked to supply. Customer sales contract lines are linked to vendors purchase contract lines by use of partial deliveries in order to fulfill the demand of the customer. Partial deliveries are combining data from different places in Agrio when linking demand and supply. From the partial deliveries also multiple reports can be printed to instruct for example the transport company.

Linking Demand and Supply

In Agrio, Sales Contracts can be created. On the sales contract the quantities requested by the customer are registered including other data as, size, loading address etc. With setting up sales contract(s) in the beginning of the season we can forecast the required demand (see topic forecasts & reservations). During the season the customer can call of the required quantities from the sales contract agreed and setup at the beginning of the season. The graph below shows a sales contract with Bioland Agri Business, including the demand of 100.000kg 25JEP12/55.

To fulfill the demand of the customer there also has to be a supply side. This is done by setting up a purchase contract. On the purchase contract, the quantities which the vendor (based on estimations) can deliver during that year are registered. Below the purchase contract with Landbouwbedrijf van Doorn is shown.

Now there is demand (sales contract) and supply (purchase contract) with a partial delivery a link between these two can be made. The partial delivery can be made directly from the sales contract (select the button “warehouse” in the ribbon), but can also be created separately. In this example it is done separately. Under “Lot & Logistics” we can select “partial deliveries”. From here we can create a new partial delivery by selecting

new. When doing this we have to fill in for which customer we want to make the partial

delivery.

Now the partial delivery “MAG21-00066” is created. To link the partial delivery to a sales contract sales lines have to be selected. This can be done by selecting “get sales lines” in the ribbon under the button “prepare/release”.

Then a screen with all the different sales lines opens, here we select the sales line(s) of the Sales contract CP-VCN21-0040 we just created. We now assign 12.000kg to the partial delivery just created. In this situation we select one sales line but it is also possible to select multiple sales lines which each its own quantity. Then one partial delivery fulfills multiple sales contract lines.

On the partial delivery card the requested 12.000kg in 25JEP12/55 is shown, now supply can be selected to deliver the required quantities to the end customer. This can be done under “Lot” and then click “select lot” as also can be seen below:

- A sorting and bagging order is performed on the purchased quantity. To sort it in the right size 35/55 and bag in as 25JEP12/55, this is not described in detail in this topic because it relates to the topic “process orders”.

When clicking “select lot” the screen below opens, where we can select a lot as supply for the partial delivery. On the right also filters are shown, it is possible here to add or delete filters to make it easier to select the required lot. In this example filters are applied to select the right lot. For this Partial delivery only one lot is selected as input for

the required 12.000kg in 25JEP12/55. However it is also possible to select multiple lots as supply. It can be that for example two lots are available and they both contain 8.000kg so in total 16.000kg. Then it is not possible to fulfill the demand with one lot, so the user has to select both lots and determine how much of each lot is selected to fulfill the demand of 12.000kg.

When “ok” is selected the supply and demand are linked on the partial delivery. This can be seen in the graph below.

In this situation a sorting and bagging order was performed on the purchased potatoes, to split them in the right size and bag them correctly. As a result of that activity performed in advance of making the partial delivery, the partial delivery has directly the status “ready for delivery”(1) when selecting the lot. However it can also be that you select a lot that is still field crop on the lot selection. Then a sorting and bagging order can be performed from the partial delivery directly (2).

Partial Delivery Documents

The partial delivery now has the status “ready for delivery” if everything is correct the status can be set to “release for delivery”, this can be done in the ribbon under the button “delivery”. When the partial delivery has the status released. Different documents can be printed in order to instruct for example the transport company. This can be done from the “dossier” in the ribbon and the most often used documents can directly be printed from the partial delivery when selecting “Print/Partial delivery” in the ribbon. A lot of documents can be printed from the partial delivery, the most important ones are summarized below:

- Loading document

- Transport order
- Unloading document
- CMR
- EUR1
- Delivery note
- Bill of Lading
- T2L
- Growerlist
- Packing list
- Atlas Export
- GMO

When the transport company is instructed and the quantities are delivered to the customer, the partial delivery can set to status “finished”. When the partial delivery is finished, the sales invoice can be created, to invoice the customer. This is described in the topic “Sales Invoices”.

Over- and Under Delivery

Last modified: 2023-09-25

1 INTRODUCTION

In AGRIO it is possible to turn on a setting that makes it possible to over- and under deliver the asked quantity on the Partial Delivery.

In this topic we will describe the setup of this functionality, and also how to use this.

2 SETUP OVER- AND UNDER DELIVERY

To set this up, you have to go to the AGRIO setup. In the section Warehouse you see the setting 'PD Over- and Under Delivery Check'. There are four options for this setting:

- Disabled

This means that you cannot deliver more or less than the asked quantity in the Partial Delivery.

- Under Delivery

This means that you can only deliver the asked quantity or less in the Partial Delivery.

- Over Delivery

This means that you can only deliver the asked quantity or more in the Partial Delivery.

- Under- and Over Delivery

This means that you can deliver the asked quantity, but also more and less than asked in the Partial Delivery.

3 USE THE OVER- AND UNDER DELIVERY

In this example we have selected the option 'Under- and Over Delivery'. When we create a new Partial Delivery, you will see that there is a new button in the screen, called 'Over- and Under Delivery Allowed'. When you check this checkbox, it is possible to deliver more or less.

In the example above, there is asked 10.000kg in the Partial Delivery. But we selected a lot with 3.500kg. As you can see, the delivery status is 'Ready for delivery'. This means that the Partial Delivery can be delivered, even if the asked quantity is not reached. When we post this Partial Delivery and create an invoice for this, only the 3.500kg will be invoiced. See example below:

If you do not check the checkmark, then you will get the following error if you change the status of the Partial Delivery.

This means that the quantity (input) from the Partial Delivery Line is not the same as the quantity (input) from the lot line. By checking the checkbox, it is possible to change the status of the Partial Delivery.

An other way to get this done, is to change the quantity (input) of the Partial Delivery Line, so it is the same as the Lot Line. In this way you will only see the 3.500kg on the invoice, but you will not see the original asked quantity anymore. In this case the setting does not have to be on.

Unknown Lots

Last modified: 2023-01-26

Also referred to as Fictional Lots.

AGRIO Software supports multiple ways of handling delivery preparation. One way of handling is the AGRIO Software user deciding what lot to prepare for the delivery. Another way is the grower deciding what lot to prepare. Often when the grower decides the lot to be prepared, the lot is unknown until the grower reports back his instruction with the used lot number mentioned. The only certainty that the AGRIO Software user has, is what grower is going to prepare the delivery.

This document will explain the Unknown Lots functionality with an example as a guidance. A total of 25.000kg of variety AGRIA SEED labeled as class E in packaging Bulk will be delivered to Potato Trading Company. The grower is Bioland Agri Business.

Setup

To activate the Unknown Lots functionality, activate the module in the Segment Setup. After activating the module, new checkmarks will have appeared on the Partial Delivery card.

Figuur 1 Segment setup

Number series

Unknown lots may receive a different number than the normal lots. Configure the number series for unknown lots in the AGRIO Setup.

Figuur 2 Unknown Lot number series in AGRIO Setup

- Just like every other AGRIO Software number series, the number series may be overwritten in the Segment Setup for segment specific purposes.

Usage

Partial Delivery

The checkmark that appeared after activating the module is found in the Partial Delivery lines. For each Partial Delivery line an unknown lot may be configured.

Figuur 3 Fictional (Unknown) lot checkmark on the Partial Delivery lines

When the Unknown Lot checkmark is checked, a popup will appear in where the AGRIO Software user selects the grower. The variety and the size will have been prefilled and may be changed if needed. In our example, we fill the vendor number with the grower Bioland Agri Business.

Figuur 4 Select the grower

When OK is clicked, the Partial Delivery is adjusted. The status has changed from 'Open' to 'Lot selected' and the Lot lines are filled with the grower that was chosen previously. The unknown lot has received a lot number from the number series that was chosen in the AGRIO Setup.

- Important to know when creating an unknown lot is that an unknown lot will, just like normal lots, have a Lot Card and a Lot Inventory.

The lot number received in our example is lot number 21ULO-0067. The system also created a second lot, lot number 21ULO-0068. This second lot is created to even out the

Lot Inventory. If we would not create this second line, the Lot Inventory would be 25.000kg too high.

In the Lot Inventory, the balance (Position) is 0. This is correct, because the unknown lot does not actually exist. Furthermore, the Reserved quantity is 25.000kg, resulting in a Position after Reservation of -25.000kg. This is also correct, because the Partial Delivery requesting 25.000kg is allocated to Bioland Agri Business. In the image below we can see the two unknown lot lines.

Figuur 5 Lot Inventory with filter on Unknown Lots

If the filter is changed to the grower number, we have a different view on the Position after Reservation.

Figuur 6 Lot Inventory with filter on Grower Bioland Agri Business

If the Lot Card of the Unknown Lot is reviewed, one can see that the Unknown Lot has received the Seasonal Distribution of the relevant Variety from the Harvest Year Setup.

Figuur 7 Lot Card > Lot Inventory Sizes

Process Order

Once the Partial Delivery steps are ready, a Process Order is created from the Partial Delivery to instruct the grower to prepare the requested delivery.

Figuur 8 Create a Process Order from the Partial Delivery

A popup will appear requesting input for the Process Order. In our example, we request a Process Order for packaging 25.000kg in BULK.

Figuur 9 Configure the values in the popup

The Usage of the Process Order will be the Unknown Lot. The Production of the Process Order will be the requested delivery values. The Process Order is automatically set to the status 'Released'. Furthermore, the Process Order indicates the Usage of an Unknown Lot in the header.

Once the grower reports back the lot number used, the AGRIO Software user may choose the used lot on the Process Order.

Figuur 10 Replace Unknown Lot on Process Order

Once replaced, the Process Order shows the chosen lot instead of the Unknown Lot number. In our example we chose lot number 21LOT-0012. Next to that, the Unknown Lots have been removed. Release the Process Order again to see the position of lot number 21LOT-0012 reduced by 25.000kg.

When the Process Order is ready, it may be Finished and the Partial Delivery is automatically set to status 'Ready for Delivery' with the correct lot number.

Other

Some additional notes on Unknown Lots.

- When doing regular Lot Selections on the Partial Delivery, the Unknown Lots are excluded from selection.
- Unknown Lots cannot be reserved.
- Unknown Lots should not receive any test diggings or box valuations (manually as well as automatically).

Combi Transports

Last modified: 2023-01-26

Introduction

A combination transport (further know as 'Combi transport') is the way for AGRIO to group multiple partial deliveries and/ or transports which have the same destination.

This is especially useful for sea transports, where one sales contract (line) can consist of multiple containers, loaded on the same ship, with the same destination.

Combi transports are the solution for grouping partial deliveries and viewing or editing information to the linked partial deliveries and/ or transports.

Documents can be created based on the data from all related partial deliveries and/ or transports via the 'Dossier'. Various documents can be generated by default from the 'Dossier'

Combi transports are part of the standard AGRIO software set and will be useable by default.

Setup

Apart from assigning a number series to the combi transport, no additional setup is required for using it.

Number series

Configure the number series for combi transports in the AGRIO Setup, in the number section:

Figure 1 Combi transport number series in AGRIO Setup

Optional Setup

When creating a sales contract, it is possible to automatically create a linked combi transport by enabling the setting 'Combi Transport Sync Assoc.' in the 'Transport and Logistics' section in the AGRIO settings.

Disabling this setting will not have effect on currently linked combi transports.

Creation

A combi transport can be created in three ways:

- Manually, from [Lots and Logistics, Combi Transport List], click the 'new' button:

- Manually, from a sales contract, by clicking the 'assisted edit' button (three dots '...') on the right of the 'Combi Transport No. field (when the field is empty):

- Automatically, when creating a sales contract when the AGRIO setting 'Combi Transport Sync Assoc.' is enabled, the checkmark 'Create Combi Transport' will be enabled by default:

Combi Transport Card: sections

General

No.: Shows the combi transport number. Depending on the linked number series, this number is editable, (not) visible and or auto-generated.

Release status: shows the current release status. Can be changed by the 'Release' option in the ribbon.

Status Combi-Transport: This field shows the current status of the Combi transport. This can differ from the various linked partial deliveries/ transports.

Archived: Combi Transports can be archived, meaning they will not show up in specific places in Agrio, be can still be viewed.

Customer & Ship-to address

In this Section, The address information from the linked customer from the partial deliveries is automatically filled when all delivery lines have the same information regarding the 'Sell-to' and 'Ship-to' fields.

Vendor & Loading address

In this Section, The address information from the linked vendor from the selected lots is automatically filled when all lot selection lines have the same information regarding the 'Buy-from' and 'Loading' fields.

Harbour and Container

In this section, general information related to the harbour and ship can be entered. This information can be printed on documents.

Collection address: here, the collection address from the container can be entered. This can be either a container terminal or an harbour. This location should be known to Agrio upfront.

Harbour code (unloading): in this field, the harbour where the container will be loaded on the ship can be entered. This location should be known to Agrio upfront.

Harbour code (Destination): in this field the destination harbour code can be entered.

International Codes

In this section, information about several internationally used codes can be entered. This information can be printed on documents.

Temperature and Ventilation

In this section, information regarding transport conditions within the containers can be entered. This information can be printed on documents.

Default values

When printing documents from the 'Dossier', the documents need some general transport information. This information can be entered in this section.

Please note: when entering information in fields which also exist on the linked partial deliveries (PD's) and or transports, the information will be copied to the linked PD's / transports.

Section: Partial Deliveries

All linked Partial deliveries will be shown in this section. Also, the information in this section is editable, therefore, it is the place for editing/ entering all container-specific information for linked partial deliveries.

Also, it is possible to update the 'Delivery status' from all visible partial deliveries at once, by selecting the 'Delivery' option in the ribbon, then selecting one of the available statuses:

In the ribbon of this section, it is possible to view the card from the selected Partial Delivery:

Partial Delivery Lines

This section shows all partial delivery lines linked to the partial deliveries in the section above:

This section is non-editable. If changes should be done, it is possible to access them via the Partial Delivery section, select the correct line and press the 'card button' via the ribbon.

Transport Orders

All linked Transport orders will be shown as well on the combi transport card:

This section is also editable so data from all related transports can be easily adjusted via this section.

When selecting a line, the Transport order card can be opened by clicking the 'Manage' button in the Ribbon, then selecting 'Card':

Also, it is possible to create a new Transport Order from the combi-transport by clicking the 'Manage' button in the ribbon, then selecting the 'New' button:

This will create a new Transport order with the data from the Combi transport.

Combi transport card: ribbon

The ribbon of the Combi transport card shows a wide number of options:

Release

Enables the user to Open/ Release the combi transport. When releasing the combi transport, a check can be performed to see if all required fields have a value.

Dossier

From this menu, the Dossier can be opened, allowing the user to print a wide range of documents.

Agrio by default provides a number of available documents, such as:

- Delivery notes
- CMR
- Instructions for Bill of Landing

- Packing list

Custom reports can be added as well.

Note that the information provided to create the documents are the linked partial deliveries, partial delivery lines, lot selections, transport orders and Transport order lines.

Delivery

From this menu path, it is possible to update the status of the linked Partial deliveries or Transport orders.

When selecting an option, a check will be performed per Partial delivery or Transport order if all conditions are met. Once an error occurs, the function will stop executing (further Partial deliveries or Transport orders will not be processed) and already processed lines will not be rolled back (meaning: the new status will still be in effect).

Navigate

Navigate directly to either the linked:

- Sales contract
- Purchase contract
- Transport lines
- Lot selection lines

Show attached

View the Notes or Links for this combi transport

Page

Go to the next or previous Combi transport

Actions

Shows all available actions from the different menu paths mentioned above

Report

Directly access a number of reports (which are also available via the Dossier) for printing or email:

Sales Contract

A combi transport has a 1 – to – 1 relation with sales contracts, meaning: one combi transport can be linked to one sales contract.

A combi transport can be linked or created to/ from a Sales contract in the 'Transport' section:

Reports & Lists

Combi transports can be found on different places in Agrio. The most practical ones are mentioned here.

Combi transport list

The most complete overview of Combi transports can be found via [Lots & Logistics, Combi Transport List]:

In this list, most of the table-related information regarding to Combi transports can be viewed. Via personalization, it is possible to add/ remove columns.

Partial Deliveries List

To see if partial deliveries are linked to a Combi transport, the menu path [Lots & Logisitcs, Partial deliveries] can be used:

Sales Contract List

Since a 1-to-1 relation exists between Sales contracts and Combi transports, a column can be added to see if a Combi transport is linked to a sales contract

Web service: Query 'Combi Transport'

In order to export the available Combi transports to other applications outside Business Central, Agrio software provides a query which exposes all available Combi transports:

By default, this query is not active and can manually be made available via de 'Web services' menu.

The output is in Json and can be handled by any modern (web)application:

GNIS link

Last modified: 2023-03-21

Introduction

In different countries, crop growing data is collected concerning field crops. This data contains information related to the grower (grower number, name), the plot (number, surface) , the crop (variety, generation, plantation dates).

Companies with these fields under contract can access the data related to 'their' growers.

In France, the GNIS collects this data and sends an overview of all lot numbers (unique combination of district number, grower number, plot number and harvest year) linked to a specific (purchase) company.

Also, the FN3PT provides inspection data year-round. This data is information related to the same lot numbers: (de)classification, total size of the plot and disease information.

This information is send twice a week.

The GNIS link in Agrio can process both the GNIS (contract) and FN3TP (update) information: leading to creation of contracts and/ or updating of current contract lines.

This document describes the way of working with the GNIS link in Agrio.

Gnis link: functional purpose

The GNIS link will enable the user to import two types of files:

'Contract files': these files have a .txt file extension and contain general information about available lots for the coming harvest year.

- These files are provided by the GNIS.
- *importing and processing contract files will lead to grower purchase contract creation*

'Update files': these files have a .csv file extension and contain lot-specific updates, obtained by field tests.

- These files are provided by the FN3PT.
- *Importing and processing update files can lead to changes in:*
- *Input Quantity*
- *Class code*
- *Generation code*

Setup

When the GNIS module is enabled, a new GNIS setting section will become available:

GNIS sector code: Default sector code used when a contract is created by GNIS import

GNIS segment code: Default segment code used when a contract is created by GNIS import

Contract type code: Default contract type code used when a contract line is created by GNIS import. The contract type code is determined in the following order:

1. check if a contract Template exists for the current vendor (table 'AGR Default Contract Template', filter on vendor and 'AGR Contract Type' = 'Vendor') with matching sector, segment and harvest year. -> use the linked contract type code.
2. check if a default contract template exists for this Harvest year, Sector and Segment -> use the linked contract type code.

3. check if a default setting exists for the GNIS Contract Template in the Agrio settings, GNIS section -> use the linked contract type code.
4. check if a default setting exists for the GNIS Contract Type Code in the Agrio settings, GNIS section -> use the this one

Contract template: Default contract template used when a contract is created by GNIS import. See sequence above for determination of the used template code.

Size code: Default size used when a contract line is created by GNIS import

Create contract lines for Stains: When only mother seed information is provided, should contract lines be created when contract file is provided?

Automatic surface value on 0 value import: When a contract line with a quantity of 0 is provided on a contract file: should Agrio use a different value

Use lowest field ID for combined boxes: When different purchase lines have been merged in boxes, should the last field ID be used for new values provided by the GNIS link?

Functional use

Via the menu path [Purchase, GNIS import] the GNIS import page is available:

In the ribbon of the page, several options are available:

- Import GNIS File
- Check GNIS line(s)
- Process GNIS line
- Toggle-Ignore Line
- Marked for Deletion

Import GNIS File

This button will start the import of a GNIS file. The next screen will ask the user if an update or a contract file should be imported:

Dependent on the selected option of the screen, Agrio will read the file. Choosing a 'wrong' file will result in an error, indicating probably an incorrect file has been selected.

When the right file has been uploaded, Agrio will automatically import all the found files into Agrio and will show the lines in the GNIS import page:

Several things now happened:

- Depending on the selected import method (Contract/ Update), the file type will be associated ('Contract' or 'Update'), indicating the file type of the imported line.
- The first visible line equals the first line in the provided file.
- The 'status' field will be empty
- No Comment Lines have been created for the lines
- The 'Latest import Contract/ Update' field has been updated.
- The provided file still exists.

Check GNIS Line(s)

When lines exist, a selection of the lines can be performed. This can be a total selection of all lines (clicking one line, next pressing [CTRL + A]), or filtering the lines first, then selecting all lines. Or simply selecting 1 or some lines by holding the CTRL/ SHIFT key down.

When 1 or more lines are selected, pressing the 'Check GNIS line(s)' button will do the following:

For all selected lines with no status, Agrio will check if this line can be matched with a line from a purchase contract, based on Lot No.

This means:

- selected lines with a different status (then 'no status') will not be evaluated
- lines with no status which are not selected will not be evaluated.

After evaluation, a new status can be assigned, depending on the found match:

- 'Error': some error(s) has occurred. All errors found will be visible on the 'Agrio comment lines' section, visible by opening the info pane on the right-hand side of the screen.
- 'Update existing line': When processed, this line will change the data on the existing purchase contract line. Via the info pane, the values which will be updated are visible.
- 'Create new line': When processed, this GNIS line will create a new purchase contract line. If no contract exists for this grower, a new contract will be created.
- 'No changes': a match has been found, but this line will not update anything on the existing purchase contract line.

Process GNIS line

The same selection rules exist: this button applies only for selected lines.

When clicking this button, Agrio will perform the 'Check GNIS line(s)' functionality and then execute the suggested action.

'Execute the suggested action' will only affect lines with status 'Update existing line' or 'Create new line'. All other lines will not affect Agrio.

The 'Check GNIS line(s)' functionality is optional: the user can immediately use the 'process GNIS line' function.

As soon as a line is successfully processed, the purchase contract number is assigned to that line, so the contract can be accessed easily:

Processed: Create new line

When a GNIS import line with the status 'Create new line' is processed, the following will happen:

- When this is the first grower agreement line for this GNIS grower for this harvest year, a new contract will be created.
- the following fields will be filled:
- Vendor No and address data
- Document date (date of import)
- Purchase Doc. Type ('Grower')
- Default fields which will be filled by entering the Vendor No.
- Per import line, a new contract line will be created. The following fields on line level will be filled:
- No. (item number, determined by the first found item which matches the GNIS Sector, the GNIS Segment and has the linked variety code which has the same GNIS variety code as the import lines).
- Class (provided by import lines)
- Size (GNIS size)

- Cultivation method (GNIS cultivation method from linked grower)
- Generation (provided by import lines)
- Quantity (input) (provided by import lines)

- UOM (input) (Agrio settings: 'HA- Unit of measure Code')
- Country of origin: 'FR'
- Lot No. (provided by import lines)
- Field ID (provided by import lines)
- Short field ID (Field id without leading zeroes)

Note: only one grower contract per grower per harvest year will be created.

Processed: Update existing line

When updating an existing line, the match will be done based on an existing lot No. The update file will contain a lot No, which will be stripped from spaces. When a match has been found in existing purchase contract lines, Agrio will check if any of the following fields have been changed:

- Input Quantity
- Class code
- Generation code

If that is the case, the contract line will be updated with the newly provided data. Also, lot information (and stock positions) will be updated. Related information (such as reason for downgrading etc) will be visible via the GNIS information lines.

Toggle Ignore line

Using this button on selected lines will assign the status 'Ignore' to the selected lines. This means these lines will no longer be checked ('Check GNIS line(s)' function) or processed ('Process GNIS line function').

When the status of this line is (already) 'Ignore', the new status will be empty.

Marked for deletion

For this button to have effect, no lines have to be selected. The system will perform a check if lines added via the GNIS functionality can be deleted.

This will be the case when a line was previously added by importing a contract file and later another contract file was added. The second contract file does not contain the line provided in the first contract (based on Lot No. & Harvest year combination).

Now, the lines not found in the second file will be 'marked for deletion': showing a screen with the obsolete lines which could be deleted:

Deleting lines will result in updates GNIS import lines, indicating the imported (previously processed line) has been deleted later in the process:

GNIS Import Card

Clicking on the 'status' field of an imported GNIS line will open the GNIS import card page. This page contains all detailed information related to the imported line.

The card is divided into 7 sections, which are partially filled by the contract file, partially by the update files:

It is not possible to change any data in this screen: the imported contract/ update file provided the data.

Changes on lot card

On the lot card, there are two ways to see which GNIS information is related to the lot:

- 'Show Crop Inspection': shows a combined overview from the latest contract file & update file in one screen. This way, the most complete information can be provided related to GNIS/ FN3PT information for this lot.
- 'All Crop Lines': shows all imported lines related to this lot, so a complete overview is established of the imported data for this lot.

GNIS web service

In order to get the information imported into the GNIS Import table, a web-service can also be used.

In order to access the web-service, it has to be added to the list of available web-services, by searching for 'web services'.

Next, a new line can be added, with the following data:

- Object Type: 'Query'
- Object-id: 11270488 ('GNIS Import AGR')
- Service name: a valid servicename, containing no spaces or special characters.
An example could be 'GNISimport'
- check the checkmark in the 'Publish' column.

Go to the previous line, and see Business Central automatically generate the URL which can be used to access the data in the 'OData V4 URL' column. This URL can be used in an external program (such as MS Excel, Power BI, etc) to retrieve the data on the table. In the example above, the URL could be:

`http://localhost:7048/BC190/ODataV4/Company('HW%20Food%20group%20-%20test')/GNIS_import :`

- 'localhost': the server BC is running on
- ':7048' the default Odata port
- 'BC190': the instance of the BC installation
- 'OdataV4': it's an Odata data set
- 'Company('HW%20Food%20group%20-%20test')': Because this query is available on the 'HW Food group - test' company
- 'GNIS_import': the query's name.

When accessing this url, credentials will be required: this should be the used credentials to access Business Central.

The URL can be filtered by the default filter possibilities available for Odata, limiting the returned data set/ visible columns, for example:

`http://localhost:7048/BC190/ODataV4/Company('HW%20Food%20group%20-%20test')/GNIS_import?$filter=Original_Lot_No_%20eq%20'F112066900322'` to only show lines for the 'F112066900322' original lot No.

Corrections - Consumption

Last modified: 2023-01-31

See also Topic 'Packaging'.

Corrections (Consumption)

For the consumption process the use of packaging will be used differently. Items will be created, purchased and received at location by a transport order. In this way AGRIO keeps track of the packaging inventory, it's similar like the inventory of the "main/food" products. For the existing inventory it might be needed to perform corrections, this will be discussed in more detail below.

Journal - Corrections

The item "foil" was received by means of a transport order from supplier 1106 to location Zwolle and there is now 9.880 meters in stock of lot *0065 (10.000 MT had been received, but 20 MT has now been written off due to a packaging order).

According to the purchase contract, there are still 5.000 at the supplier, which will be received on location in the future.

Now it turns out that the actual number on location Zwolle is not 9.880 but 9.750. This means that a correction of 130 MT is required.

Lot Journals

Open the journal and select "lot selection"

In the dialog screen, choose the correct lot number *0065, then the line will be adopted:

Adjust the "new position", the difference is then automatically filled:

This can then be "posted". Result lot card, the quantity is now set to 9.750.

If you click on this, you will see the underlying entries:

Undo Transport Lines

This action can be executed from the transport order when an invoice has been posted and should be used when the invoice and inventory should be corrected in AGRIO.

Example: In this case a transport order is finished and invoiced towards the customer, it concerns 1.000KG. The customer let us know that not 1000KG but 800KG was received and therefore a correction is required.

Options:

With the function "undo transport lines" the transport order can be corrected, which will result in an additional/correct invoice. When you click on this function the following scheme is displayed;

Undo Transport from vendor and to customer

In this case the transport should be corrected towards the vendor and customer. If only a correction is needed towards the vendor or customer, then select one of the other options.

Subsequently the following notification will pop up (after selecting OK):

This means, do you want to create only a correction for the -200 KG which will result in a credit note or do you want to correct the full -1000KG and create a new line for the actual 800KG.

In this scenario we choose yes. The lines are created (after the original transport order no. a "/" and number will be added from low to high – normally this will be "1")

Here the user can change the new quantity to 800.

The additional packaging codes are automatically adjusted as well:

When all is correct, finish the transport order.

Then the inventory of that lot number will be updated as well.

Create a new invoice batch, this will result in a batch with 2 transport lines:

Create the invoice, then the correction and the new price are calculated:

Only undo transport from vendor

In this scenario a purchase invoice is posted for 100 25JEP12/55 (=100KG), but a correction is needed.

Select location "Credit" (because we need a "code unloading")

Do not create new transport lines, the following transport correction order is then created:

Change the quantity from -100 to -25 and finish the transport order

Run the purchase invoice batch:

Create the invoice, this will result in an unposted purchase invoice (product). However, because the amount is negative it will result in a posted purchase credit memo (products)

This will affect the available inventory of that specific lot as well in the lot overview. This applies also for the "packaging balance" if that is activated for the packaging item (s).

Creditnote from Posted Invoice

This method is only useful when it concerns a cost invoice because there is no inventory correction behind it.

After you create the "corrective credit memo", adjust and check the "sales cr. Memo" before you post it into the system. A preview of the posting is useful.

Packaging

Last modified: 2023-01-31

Introduction

This topic handling the registration / handling of the processes surrounding packaging and packaging in AGRIO Software. In AGRIO terminology, packaging is equivalent to a 'product carrier', for example pallets, crates, roll containers and big bags. Packaging is often not reusable and concerns, for example, foil, cardboard boxes, wrappers, labels, etc.

In AGRIO Software, the same item can be purchased and sold in combinations of packaging and packaging. In order not to create a new article in the article file for every possible combination of packaging and/or packaging, "Input units" are used. Up to 4 packaging levels can be defined for each input unit.

For companies in the agricultural sector, the handling of packaging is important, both towards the customer and towards the grower/supplier. That is why AGRIO Software has functionality that handles the process of handling packaging.

Two things are important when receiving and/or delivering goods containing packaging/package:

- Will a packaging stand be maintained?
- Will the packaging be charged on a settlement of an invoice?

The packaging status is the amount of packaging that you as a company have or owe to another company.

Chapter 2 explains how AGRIO Software can control whether the receipt / delivery of packaging should end up in the packaging position.

Chapter 3 examines which packaging entries are created based on the transport order types and shows how the packaging purchase, packaging journal and packaging balance work. This is mainly in use for the Seed process.

The last chapter describes how the lot journal can be used and how financial & inventory corrections can be made in AGRIO.

Input UOM Code - Packaging

In AGRIO Software, multiple Input UOM (BASE) can be defined per item, all with their own packaging hierarchy (up to 4 levels).

Figure 1: Item unit of measure setup

In the example, the Entry Unit 25JEP12/50 stands for a hierarchy, where 50 jute bags of 25Kg each are on an EP12 pallet (so a total of 1250 kilos).

With regard to unit setup:

1. Items can fall into an item category. To prevent the exact same units from having to be set up for each item, Input UOM (BASE) can also be set up per item category. These units are then automatically applied to all items that fall into the relevant item category.
2. In the example above, the 'Factor Input UOM (BASE)' is set to 1. This means that the factor between unit 25JEP12/50 on the one hand and the base unit of the article (KG) on the other hand is 1. When in the system 25.000 25JEP12/50 sales are made, then in this case 25.000 kilos is meant. If in the same example the factor would be 25, and you buy 1.000 x 25JEP12/50, then 25.000 kilos is also meant. With this setting it can be controlled whether the user will enter the number of kilos or the number of 25Kg bags.

3. The packaging factors serve to calculate the number of pieces of packaging. When 25.000 Kg is purchased in the example, 1.000 jute bags and 20 pallets are needed. During machining and transport, these standard quantities can be adjusted with the actual loaded quantities of packaging.
4. Sometimes a factor between an Input UOM (Base) and the base unit is not fixed. In this example, this is the case with the factor between the unit HA (Hectare) and the base unit KG. The factor may depend on the variety, but also, for example, on a certain region. For example, Flevoland may have to use a different standard yield per Hectare than in the north of France. In that case, using a Scale offers a solution to calculate the yield per hectare for a particular purchase contract.

Packaging Setup

AGRIO Software has so-called 'Packaging articles'. This is an item from the item table on which the packaging position is recorded. A Packaging item can be linked to each packaging code (see Figure 2). Often the packaging code and the packaging item will have the same code, for example Jute25 or EP12 (Europallet 1200x800). Figure 1 shows that EP12s, for example, are found in many combinations: jute bags can be on them or Big-Bags etc. Of course, that doesn't matter for the packaging stand. Each packaging item is registered (if set), i.e. both the pallets and the Big-Bags. The packaging position can only be registered if a packaging item is linked behind the packaging code.

Whether the packaging position is recorded is determined in the packaging settings:

Figure 2: Packaging setup

The check mark 'Create packaging entries' determines whether a packaging position is kept for the relevant packaging code / relationship (group) on the purchasing side and/or sales side.

The packaging balance of a company is the total of the packaging items that are created by AGRIO Software when booking transport orders (inbound and/or outgoing).

The packaging position is currently tracked in AGRIO Software on the order customer (sales) or the order supplier (purchase).

Transport Types - Packaging Entries

All packaging entries are created when the transport type is from vendor to customer. This is not (yet) the case when using "locations" (Consumption process). Below a few examples:

Vendor -> Customer transport order.
Then 2 packaging entries are created.

Location -> customer transport order

Then 1 packaging post is created.

Vendor -> location transport order

Then 1 packaging post is created.

In the example below we assume the box packaging with the number of 1 illustration. The numbers in black are already made in AGRIO, this does not apply to the numbers in [blue](#).

Reverse the transport order lines, then the transport type remains the same only the (packaging) quantities become negative.

Packaging Purchase | Inventory Location

AGRIO Software contains functionality to purchase packaging, the so-called packaging orders. The reasons to create a special purchase order for this and not to use the standard Dynamics NAV purchase order for this are:

1. You want to be able to purchase packaging/packaging with the delivery address at one of our own locations, as well as purchase where the packaging/packaging is sent directly to growers/customers by the supplier.
2. It must be possible to create packaging entries directly from this order, with which the packaging balance at the supplier/customer changes or whereby the stock quantity in our own locations is updated.

This can be done by the use of journal "packaging purchase". This is the stock that is at your own location. In this example, the stock increases with 1000 at location Zwolle as a result of start balance:

Open the batch. Here you are able to define the specific correction.

There is no further relationship with transport orders or other existing transactions within AGRIO.

Packaging Journal - Correction

Finally, AGRIO Software has a packaging journal, in which changes in packaging can be recorded. In the example below, for example, the delivery of 4 Boxes to Landbouwbedrijf Van Doorn is recorded. This affects both Van Doorn's packaging balance (+4) and our own stock (-4).

Open the “packaging journal”. Here you can define the correction, in this case we chose “shipped”. If that is correct, then you can post this into the journal.

Packaging Balance

After multiple transactions and transport orders the packaging balance of a contact and our own location becomes insightful. Navigate to “packaging balance” and click on the related contact no to see the current packaging balance.

Inventory Contact

You are able to click on the “number” to see the “entries” that are responsible for this balance.

This works for each contact when checking the balance.

Own location inventory

Click on “packaging inventory”:

Then the overview is shown for the inventory that is posted on the location(s):

Entry in the background:

Packaging Return

At the moment it is only possible to make corrections by using above journals, like processing the return packaging per customer, supplier or location. The goal is to improve this section in the future, meaning that for each transport order packaging returns can be defined and processed.

Versioning

Introduction

Documents in Business Central are being generated on-the-fly. This means: when a user requests a document (by clicking on 'Print Document' for example), BC will look at the available data and the report settings and shows the document. This can have an undesired effect: because both the data and/ or the report settings can change over time, a different document will be the result of the 'Print Document' action.

Agrio presents the possibility to save a document when generated to create a version history over time. The generated document will be stored in the system and can be opened/ downloaded at a moment later in time.

Settings

Via [Settings, General Settings, Agrio Settings] in the 'General' section the Yes/ No field 'Use versioning':

After enabling this setting, the menupath 'Versioning templates' will become available. In this page, the setup of Version documents will be done.

The settings screen for version control will become available:

Create a new line for each unique combination of Document, Document code and view string.

1. At the moment, the documents made available are Transports, Partial deliveries and Process orders.
2. The Document code is filtered by the selected document on the 'Versioning table' column. The visible lines are the available lines in the report setup, which are unique per

sector, segment and document code. Keep in mind that different documents can be set-up for different sectors/ segments. those combinations should also be made available in this screen.

3. View string: It is possible to generate a different report, taking the document data into account. For example, Process orders with the Process Type 'SORTING' can have a different report than the process order with the Process Type 'BAGGING'.

Practical use

When properly set-up, the button 'Archive version' can be used on the available documents. This button is visible in the ribbon of the document card. By selecting this action, a new version document will be created and saved in the database, taking the versioning template settings into account:

By creating a new version, a .pdf document will be stored and the number of 'Archived versions' will be increased by one. By clicking the quantity field, the version history of this document will be shown:

License module

Last modified: 2023-07-17

Introduction

In Agrio software, it is possible to make use of the license functionality. This functionality

This is a part of the Base AGRIO app, but by default not available. A subscription is needed in order to activate the module.

The License module can be used by AGRIO users in two ways:

1.) Track license costs for sales.

The user is a licensee: sells products which are under license. Goal of use is to get an overview of license fees to pay.

This will be done based on transported products linked to license agreement contract lines.

2.) Create license invoices based on contracts.

The user is the owner of a product under license, other companies have to pay a license fee per sold quantity.

1

Chapter 1

1.1 setting up the license module

1.1.1 Activation of the module

Via [Settings, General Settings, AGRIO settings] in the 'module' section, the option 'use license module' should be turned on:

1.1.2 Set-up number sequences for licenses and license agreements

Create two new number sequences: one for licenses and one for license agreements.

Via [Settings, General Settings, AGRIO settings] in the 'Number' section, fill in the fields 'License Nos.' and 'License Agreement Nos.'

1.1.3 Enable the use of licenses on sector level

Via [Settings, Sector] enable the checkmark 'use license module' for the applicable sectors:

1.1.4 Enable varieties which are available for commercial sales/ purchase

When the license module is activated, a check is done for all sales orders, sales invoices, purchase contracts and purchase invoices whether it should be possible to use a variety with a price ≤ 0 .

By default, all varieties are disabled and no harvest year code is filled for purchase. This means: no commercial sales can be done and no purchases can be done for any variety.

Via [Settings, Sectors] a sector can be selected. With the 'varieties' button all varieties for this sector are listed.

Managing a variety opens the variety card, which now looks like this screen:

The options 'Available for commercial sale' and 'Purchase: available from year' are now visible.

For varieties which should be commercially available, change the value to true.

for varieties which should be available for purchase, fill in the minimum harvest year from which this variety should be purchased.

1.1.5 Set-up one or more Price corrections

In order to create entries when invoicing sales/ purchase contracts, Price corrections should exist. If multiple situations exist (for example, posting license revenue on a G/L account 'License revenue domestic' and 'License revenue non-domestic') price corrections for each situation have to be created.

Be aware that the linked G/L account of the price correction can be used in a sales invoice as an incorrect setup of the G/L account will block license agreements from being created.

1.1.6 Create license types

When creating a license, a license type can be selected. Via [Settings, General Settings] Master data no. (License type) new License types can be created:

- **Code:** The code which will be visible when choosing a license type
- **Description:** The description from the license type which will be used.
- **G/L Account No.:** When creating invoices for license agreements, the G/L account of the license type will be proposed for the invoice.
- **VAT Prod. Posting Group:** When creating invoices for license agreements, the VAT posting group of the license type will be proposed for the invoice.

1.1.7 Optional: Set-up attachment types

When linking attachments to licenses, it is possible to set an attachment type for that attachment. This way, attachments of a certain type can be grouped or easily found.

This can be done via [Settings, General Settings] Master data no. 134 (Attachment Type):

1.1.8 Optional: set-up license status options

When creating a license, it is possible to set a status for this license. This status can be company-specific, based on the available statuses in the sector settings:

Via [Settings, General settings, Sectors] the button 'Sector Dependent Setup' will open the overview of Sector-specific settings:

In table 137 (License status), the possible statuses can be entered:

1.1.9 Optional: set-up regions

In order to make use of the world/ region/ country designation, regions can be used to determine a specific set of countries. For example, the region 'ASIA' can be created and linked with a set of countries which have the same (geographical) characteristics.

On the license card and/ or in license agreement lines, the regions can be used.

1.2 Create licenses

Via [Licenses, Licenses] with the button 'new' a new license can be created:

1.2.1 License screen layout

When creating a new license, the following screen opens:

Ribbon

a Release: makes it possible to actually use the license. Checks several things:

- o Is the 'start date breeders' right' filled?
- o Is the combination of Variety, country and start date breeders right unique?

Also, all fields will be locked.

a Open: all fields will be editable again. The license cannot be used anymore in license agreements/ other

- a Show attached: show attached notes/ attachments

Section 'General'

- a Code: can be automatically generated, or entered manually. This code is unique.
- a Description: Give a more detailed insight in what this license is.
- a Type: a selection between 'Farm Saved Seed', 'Royalty' or 'Market fee'.
- a Released: can be used in overviews to see if the license can be used.
- a Sector code: Selection of sectors where 'use license module' is true.
- a Variety: selection of all available varieties for the selected sector.
- a Country: the country code where this license is being used.
- a Price correction: When generating sales invoices, the linked G/L account and VAT posting group of this price correction will be used.
- a Status: Selection of the available statuses in the License Status table, as described in [the setup](#).
- a ARD Number: possibility to enter an ARD number for informational purposes only.
- a First commercial sale: date of the invoice line where the first commercial sale (oldest invoice line with this variety – country code combination with a price <> 0) is done.
- a Start date Breeders' right: obligatory field, should be filled when releasing this license.
- a End date Breeders' right: date field for informational purposes.
- a Message on outgoing documents: When true, outgoing documents containing lines with this variety- country code combination will show a pre-defined message.
- a Total amount: the sum of all entries used for this license.

Section 'Geographical use'

When entering license agreement contract lines, a check if done if a country/ region/ 'world' can be designated. In order to do this, a released license has to exist with a region linked to it. This region can be a specific country, a region of countries or 'world'.

The order of linking a license code to the license agreement line is:

- a Country
- a Region
- a World

This means that when a variety and a country are entered in the license agreement lines, a link to a license will be made, first looking for a license with the entered country in the 'country' field. If nothing is found, a check will be done if the country can be found in the linked countries in the 'Region' field. If nothing is found, a check will be done if a license exists for the variety with the 'world' option checked on. If still nothing is found, no license will be linked.

Attachments

It is possible to attach files to a license. Files can be any kind (extension is not relevant), but are limited to 2047 MB each.

In addition, when the [attachment type table is set-up](#), an attachment type can be specified.

Notes

Notes can be added by a user, leaving a comment for this license.

1.3 Create license agreements

Via [Licenses, License agreements], a new license agreement can be created:

1.3.1 License agreement screen layout

When creating a new license agreement, the following screen opens:

Ribbon

- Release: makes it possible to actually use the license agreement. Checks several things:
 - Is the 'responsible' field filled?
 - Is the 'contact' field filled?
 - Are the Start and End date fields filled?

Also, all fields will be locked.

Also, in the license agreement lines, a check for an existing released license is done for this country – variety combination. If so, the license code is filled.

- Open: all fields will be editable again. The 'Generate Sales invoice' button is disabled
- Generate Sales invoice: based on the selected license agreement lines, a sales invoice is generated.

This button will be available when:

- The license agreement is released
- The license agreement lines have a linked license
- The linked license on the lines are released

General

- Code: can be automatically generated, or entered manually. This code is unique.
- Description: Give a more detailed insight in what this license is.
- Responsible: an internal sales/ purchase person.
- Contact: a contact from the contact list.
- Contact person: a contact person from the contact list, filtered by the selected contact.
- Contract type: Sales/ Purchase. When 'Sales' is selected, a sales invoice can be generated. When 'Purchase' is selected, the tracking of sales can be activated
- Released: indicated whether this license agreement can be invoiced.
- Start date: for informational purposes
- End date: for informational purposes
- Data ready by: for informational purposes

- Currency: currency used when generating sales invoice
- Apply price corrections: when checking this field, this license contract will be used (when applicable) to apply a price correction on a matching sales contract line.

License agreement lines

- Sector: selection from sectors where 'use in license module' is true
- Segment code: selection from available segments from selected sector
- Variety code: selection from available varieties from the selected sector
- Harvest year: selection of available harvest years from the selected sector – segment combination
- Country/ Region/ World: determines two values:

The used license code for this license agreement line

The used price correction on the sales order line (if 'Apply Price Corrections'-option is checked on in license agreement).

- Size/ cultivation method/ Sub customer:: additional (optional) specifications for this agreement line.
- 'From class' and 'To class': determines the class from and to which the filter should/ can be applied.
- Price type: selection between 'fixed' and 'matrix': when 'fixed' is selected, the 'input price' field is available. When 'matrix' is selected, the 'Price code' field is available.
- Input price: available and required when 'fixed' is selected in 'Price type' field
- Price code: available and required when 'matrix' is selected in 'Price type' field
- Price UOM: required in order to determine price quantity.
- Expected Quantity (Input): Used for budget reasons only.
- Realised Quantity : Based on this column, the quantity column in the generated invoice will be filled.
- Input UOM: defines factor for the 'Realised Quantity' column.
- Weight UOM code: default UOM from Price UOM.
- Invoiced amount: Total posted invoice amount for this license agreement line.

1.4 Licenses: Sales contracts

1.4.1 Check for commercial availability

When the price in a sales contract line is changed, a check is done if the selected variety is commercially available (variety settings). If a price is used $\neq 0$, an error message appears as shown below.

Editing the price lines (changing price back to 0 in price lines, not in order line) back to 0 will resolve this message.

Also, setting the 'commercially available' setting to 'true' in the variety settings will prevent the error from showing.

1.4.2 Automatic linking of license code in Sales contract line

When the combination of the sales contract 'ship-to country' and the used variety in the sales contract line matches an existing, released license, the field 'License code' and 'license agreement' will be filled with the matching license:

1.4.3 Automatic addition of price correction

When the option 'Apply Price Correction' is active on the found match between the ship-to country and the variety, a lookup will be performed, based on the ship-to country of the sales contract in the following order:

1. If a line is found with the same country,
2. If a line is found with a country which exist in a region,
3. If a line is found with the 'world' checkmark on.

When one of the above conditions is true, a price correction will be automatically added to the order line with the price and price factor of the matching license agreement line.

When changing the ship-to country, this check will be done again and will overwrite the current price correction.

Example:

Released license agreement for customer 'A', variety 'X' has the following lines:

Creating a sales contract line for variety 'X' for customer 'A' will result in an additional price correction:

- When ship-to country is 'Germany', €27 /TON will be used
- When ship-to country is 'China', €25/TON will be used*
- When ship-to country is empty, no additional price correction will be used.

*assuming the country 'China' is added to the 'ASIA' region, please note: this is done [by manual setup in the master data table](#).

Complaint registration financial settlement

Last modified: 2023-04-03

Introduction

Currently the credits are created based on a correction transport (undo transport lines) or from a posted invoice. With the new functionality both can be created from a partial delivery where reason codes are required. This gives more insight about why a credit is created and it will simplify the process.

If there are situations that are not covered, please us know.

Fin.Settlement from Partial delivery

This functionality is default disabled in AGRIO. If you want to apply it for a specific segment then activate the following setting:

After this the fields will become visible, and the system will validate it during specific actions.

After activating or deactivating the setting, it might be needed to refresh the page (or logout) before noticing the change.

Setup - Credit reason codes

Navigate to "credit reason codes".

Enter the general code and "credit reason sub codes". Define if there is default value and whether the price corrections should be deleted when generating the invoices.

At general you can activate "default remove price correction". If you then enter new sub codes then the checkmark will be set automatically.

Financial correction from partial delivery

Fill in the credit reason codes

At the partial delivery line the credit reason can be defined. In this case the credit reason sub code is filled in automatically.

Create a financial correction from the partial delivery

The following notification pops up:

- Create credit nota = Based on the posted sales invoice a credit will be generated (financial correction)
- Undo transport line(s) = Needed if the lot inventory should be updated as well (returned goods)

Financial correction from partial delivery (Credit nota)

Create credit nota

When you click on "create credit nota":

Choose yes. All lines from the posted sales invoice are taken over, including the price corrections:

Change the sub reason code on the partial delivery (including the deletion of price correctins), then the result is as follows:

Post the credit memo:

Change the reason codes:

Enter the right values and click on OK:

Updated posted sales credit memo (products)

[Financial correction from partial delivery \(Undo transport lines\)](#)

Undo transport line(s)

When you click on "Undo transport lines"

Click on OK (depends on situation) and define if new transport lines should be generated. In this case, select NO.

Transport card is opened and values are taken over. When finishing this correction transport, this can be collected by the invoice batch.

Example:

Other:

Notification when reason code is empty at the partial delivery line

Create credit from posted sales invoice

At the posted sales invoice the following fields are visible and should be entered before the credit can be generated.

Create credit from posted sales invoice when credit already exists

When a financial credit is created from the partial delivery and there exists already a credit memo, then the following notification will be shown:

If it's completely credited, then its not possible to create another one.

Prepayment & correction

From the sales contract a prepayment invoice can be created. When the partial delivery is delivered the sales invoice is created minus the prepayment.

That invoice is linked to the partial delivery and will be used for crediting.

BI TABLE

This table includes as well te credit reason code and credit reason sub-code

Invoicing (Purchase & Sales)

Last modified: 2023-01-31

Introduction

This document explains the steps of creating a purchase / sales invoice. The steps are similar for purchase and sales.

2 additional documents are available for specific invoicing topics:

- [Prepayments](#)
- [Sales seed material](#)

Invoice Batch

The invoice batch for sales and purchase do work in a similar way.

The process steps are also the same:

1. Agrio will collect the data for the selected type of invoice (done in the invoice batch functionality)
2. The open transport lines and the related batch invoice lines are shown
3. Select the invoice batch line you want to create an invoice for
4. The concept invoice is made
5. Final check of the concept invoice. Make it final by posting the invoice.

Select from the menu the Invoice Batch Purchase option

Choose the type of invoice.

For the description of the prepayment Invoice, see the Topic Document for Prepayment.

Based on the selected type of invoice, a selection can be made:

The new batch lines will appear. To see the details, open the line:

Here you can check the invoice transport lines, and the invoice lines that will be created when an invoice is made.

If the invoice batch line is not correct, the invoice batch line can be deleted from the batch.

NB: this is only possible if the unposted invoice is not created.

Is the unposted invoice already created, delete this invoice first (and then delete the invoice batch line)

The unposted invoice will be created by clicking:

The unposted invoice is created. In the invoice batch list, the invoice number is mentioned in the column 'Unposted document number'.

Unposted Invoice

In the previous step, the unposted invoice is created. The invoice can be found at Purchase Invoices (Products).

In this stage you can check the invoice.

When OK, the invoice can be posted and made final.

If an approval flow is in place, you can request approval. After approval is given, the invoice can be posted.

Post Invoice

After posting the invoice, the unposted invoice line will disappear in the invoice batch.

Also the unposted invoice will disappear as 'unposted invoice'.

When the invoice is NOT OK, the invoice can be changed or deleted (and after deletion, the invoice batch line can be deleted).

Sales

As mentioned before, the sales invoice process is exactly the same:

Start the invoice batch sales

Make a selection

Invoice batch is created. Open the batch line:

Check the line(s).

When ok, an unposted sales invoice can be created:

Check the unposted sales invoice

When ok, make invoice final by posting the document

Match Document Capture Invoices

Last modified: 2023-01-31

Match Invoices Document Capture Invoices with Agrio Transport Lines

Introduction

In the potato business purchase invoicing is primarily done based on self-billing. However it can be that a vendor sends the invoice by himself. Besides that for packaging it is common that the invoices are send by the vendor itself. In order to see if the received invoice is correct (prices, quantity etc) a match should be performed with the transport lines in Agrio. If the quantity or prices on the received invoice do not match the transport lines the quantities and/or price can be adjusted on the transport

lines. Or the vendor can be contacted to send a new invoice or credit note. If the invoices matches the transport line(s), an Agrio invoice can be created and posted. This Agrio invoice is linked to the received and captured invoice from the grower.

Capturing Invoices

Attention: to be able to work with the matching functionality correctly, your language should be set to “English (United States).

When receiving the invoices of the ordered products these product have to captured by using Document Capture. Default Document Capture is primarily used to capture cost invoices. In Agrio we also want to capture product invoices with Document capture and match these with the transport lines in Agrio. Therefor correct configuration of Document Capture is needed.

Flow Matching Invoices

To get an easier understanding of how matching works in Agrio, a visualization is show below:

Setup Number series for Document Capture

It is required to set a number series for the Posted Product Invoices captured by Document Capture. With this you can make a distinction between the posted product invoices from self-billing and the posted product invoices captured by Document Capture. In this example, the number series for both self-billing and captured invoices are the same.

Fields required to capture a Product Invoice

To capture a received product invoice in Agrio correctly by use of Document Capture, the templates used for recognizing and capturing the invoice have to be configured. We

have to create additional “fields” for capturing the invoices and set the configuration of these fields correctly.

The following headers have to be created this specific sequence is required on the templates!

- Invoice Type
- Harvest Year
- Sector
- Segment
- Status

Invoice Type

The Invoice Type header has to be created, to define what type of invoice it is. Default it is a “cost invoice” so when you receive a product invoice you have to indicate that it is a Product Invoice. Please see below how to setup the header “Invoice Type” correctly. Please be aware that the language you use when working with AGRIO has to be English (United States) to capture the product invoices correctly.

1. Code: has to be “Invoice Type” (visible in the top when this header was already created)
2. Field Name: Invoice Type
3. Required: Yes
4. Formula: Product Invoice (capitals required) enter the value as a formula if you know that the template you create is used for capturing product invoices received from the vendor. Then you do not have to enter this every time manually when receiving multiple product invoices from this vendor.
5. Data type: Text
6. Field in Purchase Header: Invoice Type (No. 11270506)
7. Field in Purchase Line: Invoice Type (No. 11270700)

Harvest Year

1. Code: Harvest Year Code (visible in the top when this header was already created)
2. Field Name: Harvest Year
3. Required: Yes
4. Formula: 2021, enter the value as a formula, then you do not have to enter this every time manually when receiving multiple product invoices from this vendor.
5. Data type: Text
6. Field in Purchase Header: Harvest Year Code (No. 11270500)

Sector Code

1. Code: Sector Code (visible in the top when this header was already created)
2. Field Name: Sector Code
3. Required: Yes
4. Formula: Potato/Packaging, enter the value as a formula, then you do not have to enter this every time manually when receiving multiple product invoices from this vendor.
5. Data type: Lookup
6. Source Table: Sector (No. 11270530)
7. Source Field: Code (No. 1)
8. Field in Purchase Header: Sector Code (No. 11270501)

Segment Code

1. Code: Segment Code (visible in the top when this header was already created)
2. Field Name: Segment Code
3. Required: Yes
4. Formula: Food/Seed/Packaging, enter the value as a formula, then you do not have to enter this every time manually when receiving multiple product invoices from this vendor.
5. Data type: Lookup

6. Source Table: Segment (No. 11270531)
7. Source Field: Code (No. 2)
8. Field in Purchase Header: Segment Code (No. 11270502)

Status

1. Code: Status (visible in the top when this header was already created)
2. Field Name: Status
3. Required: Yes
4. Formula: Open, when receiving Product Invoices which you want to match, this is mandatory.
5. Data type: Text
6. Field in Purchase Header: DocCapture Invoice Status (No. 11270901)

Capturing the Invoice

When the required fields are created, the user can capture the received document. Below you see an example of an capture invoice.

Matching with a Transport

When the invoice is captured it will become visible under “Purchase Invoices (Product-Doc.Capture)”.

When opening the Captured Product Invoice from this screen, you can match the invoice with a transport. By clicking “Match Transportlines”, by selecting this button the system will look for transports made. It automatically filters on Vendor Name, Sector, Segment and Harvest Year.

When “Match Transportlines” is selected, a new window will open with the transports within the filter.

Here you can look for the matching transport based on different variables, e.g. quantity, variety, class, size. When the right transport is found press “OK”. Then a new screen is opened, here you can compare the received invoice with the selected transport(s) in more detail before creating the an Agrio Invoice. Also you see the Batch difference and

if needed transport independent Entries can be added.

If everything is correct, you can create the Agrio Invoice. 1: the G/L on the product invoice line is leading, this is based on the setting from the Item Card in this example Agria Seed. In this example the G/L accounts, the captured one and the one from the transport are the same, however be aware that these can differ, then the G/L account on the purchase invoice line is leading. If the G/L accounts differ, it can also be that on the Agrio Invoice another VAT % is applied based on the item setup.

Now we have created the “Agrio invoice” based on the transport lines and matched with the captured invoice.

This Invoice is visible under Purchase Invoices (Products)

When opening this invoice you also see the original Doc Capture Doc.No

When going back to “Purchase Invoices (Doc.Capture) we also see the linked Agrio Batch, Agrio Invoice and Posted Invoice.

We are now able to post the Agrio Invoice created. When we post the Purchase Invoice

it will become visible under the posted invoices.

Posted Purchase Invoice (Products)

Posted Purchase Invoice (Product-Doc.Capture)

Approving Invoices

Document Capture provides the functionality to approve the received invoices. When using Document Capture also for product invoices which are matched with transport lines, there is the possibility to use the standard approval flow of Business Central. Under “Workflows” you can activate the workflow that is used for Purchase Documents. When this workflow is enabled, you are able to work with approval flows for the product invoices. The approvals are done after the match between the received invoice with the transport lines is done and an Agrio Product Invoice is created. This because the Agrio Invoice will create the G/L entries.

Below the different workflows are shown. An new workflow is made for approving purchase invoices, this a copy of the workflow form Document Capture with adjustments, so it works for other invoices as well.

When entering the purchaser code on the invoice, and select “Send Approval Request” an approval request will be send to the selected purchase according to the approval setup.

Now the users receives a message that “An approval request has beent sent”.

When the assigned approver now opens the invoice, he/she is able to approve or reject the invoice.

On the “Purchase Approval Entries” overview all the invoices for the assigned user are shown.

When now looking at the Purchase Invoices (DC) overview, we see that the invoice is release and approved by the user. Please be aware this doesn't mean that the invoice is posted!

Certificates

Last modified: 2023-09-19

1 INTRODUCTION

In AGRIO it is possible to create certificates and connect those to vendor cards.

In this topic we will describe the setup of the certificates. In addition, some fields will be explained and we will describe how the certificates are visible in several documents.

2 SETUP CERTIFICATES

In the vendor card it is possible to create certificates. To configure this, go to the vendor card, then select 'Process' and then 'Certificates'. A new page will open with the certificates for this vendor.

In here you can setup several certificates.

Certificate Type: here you can define the type of the certificate.

Certificate No.: here you can enter the certificate number

Description: here you can enter the description of the certificate

Valid From: from which date is the certificate valid?

Valid Until: until which date is the certificate valid?

Sector Code: for which sector is this certificate. This field can also be empty, then it will be used for all sectors.

Variety Code: for which variety is this certificate. This field can also be empty, then it will be used for all varieties.

Attachment: here you can enter an attachment.

Print on Transport (unloading): checkbox to define if the certificate must be shown on this document.

Print on Purchase Invoice: checkbox to define if the certificate must be shown on this document.

Print on Purchase Contract: checkbox to define if the certificate must be shown on this document.

Print on Sales Invoice: checkbox to define if the certificate must be shown on this document.

3 WHERE ARE THE CERTIFICATES VISIBLE?

The certificates that are created here, are also visible in the factbox of the vendor card:

In the vendor list card you can also see the certificates that are connected to that specific vendor.

Also, these are visible in the purchase contract factbox, together with the certification of the items:

The certificate is red when it is not valid anymore. If it is valid, the text will be black.

When you check the checkbox of, for example, the purchase contract, it will be visible on the contract layout like this:

Also, when the certificate is not valid anymore, it won't be shown on the documents.

Communication Module

Last modified: 2025-12-23

SETUP

It is possible to notify in rapport form if a salesman/buyer or a designated person receives a copy of the email. This can be done per rapport with a checkmark. On the document itself, like a sales invoice, are the marks: "salesman" and "designated person".

Besides that it is now also possible to define article categories, where you can link multiple rapports to these article categories.

You can later link the concerned rapports under the name: "Communication Mgt-Rapport. This can be filled in the third column.

Thereafter it is possible to notify per contact (Customer/supplier), per article category, if the email should not have been sent to the standard email address but therefor to a

another specific email address. Also there is an option which let's you choose for this category to sent it in CC or BCC form to this specific email address.

ELABORATION

Sales invoice: Sales – Blanket Order DCR (rapport nr: 11270601) On the sales invoice the next things are installed:

- Salesman: AH
- Designated user: TB
- Customer Bioland

For every category there is a known email address. Where the email address on the contact formular is leading.

Therefore it is indicated for this rapport that the salesman and the designated user are also receiving an email (AGRIO setup – Communication Mgt):

Once you create a email, this information will be correctly filled in:

Communication setup per contact - Setup AGRIO

Per rapport you can notify if the rapport falls under a certain category.

In this case we are linking the sales invoice to a category.

Navigate to contacts, and choose the within the communication setup:

In this example we make a new line, where another email address needs to be chosen as document category 008 (sales invoice) and be used in that way. The sending options are to be put on “on”, Then the AGRIO software knows which part needs to be filled in, in that case.

Navigate to the sales invoice contracts and choose email, this results in the next scenario:

This goes well! Not the standard address is filled in, but the one specific for this rapport.

When we add a extra line to the communication-setup, we later personally notify when an email is sent to that particular customer with document category 008, than later info456@bioland.com is filled in the BCC.

If you mail the contract again, than the next thing will happen:

This looks good! Related to the communication setup, the right “to” email address is filled correctly, this will replace the standard email address. Besides that you can notify per category if you would like to choose between the BCC or CC. In this case we see the email address info456@bioland.nl again the example, like it was defined.

This fields can also be filled completely, if you have defined that the salesman (CC) or designated person (BCC) should also receive an email for this rapport.

Matrices and price lists

Last modified: 2023-07-19

In this topic, the use of matrices and price lists will be explained.

Settlement per Split Size

Last modified: 2023-03-08

Introduction

In AGRIO Software, it is possible to grade lots into natural splitted sizes. Natural splitted sizes are different from actually sorted split sizes. A natural splitted size is a size that has a distribution over other sizes within that size. For example, a natural splitted size may be: 30405060. This means that 3060 is bought from the grower. The grower will not grade this size. In fact, he will hand over an estimation to the trader what he thinks he has within that 3060. The grower gives an estimation over 3040, 4050 and 5060. So the difference is, for natural splitted sizes, the grower delivers actually 3060. For actual splitted sizes, the grower would sort the 3060 into 3040, 4050 and 5060.

Recently, functionality was added to also invoice based on naturally splitted sizes. This document explains how.

Settlement per Split Size - Setup

Two new matrix variables are added to the system:

- GRADEDSIZE
- SPLIT.SIZE

The user may add these matrix variables manually to the matrix variables list.

After creating a matrix with the two matrix variables as noted above, the user may fill in the expected price per split size and graded size combination.

Figure 1 Matrix based on GRADEDSIZE and SPLIT.SIZE

Settlement per Split Size - How to use

Purchase Contract

Firstly, a purchase contract must be created. Create a contract that ranges on the outer sizes of one of your graded sizes in your matrix. In our example, the graded size is 30405060. The outer sizes are 30mm and 60mm.

Figure 2 Purchase contract on 3060

Then, add a price line of type 'Matrix'. Select the matrix that was created for the settlement per split size, in our example 30405060.

Figure 3 Purchase contract price lines

The purchase contract is now complete.

Sales Contract

As of Agrio Software version 4.9, Customers may also be invoiced in split sizes. Setup the Sales Contract to sell the Split Size and define a Matrix in the Price Lines, for example:

Figure 4 Sales Contract

Sales Contract Price Lines are filled with a Matrix based on GRADEDSIZE and SPLIT.SIZE, see chapter 1 SETTLEMENT PER SPLIT SIZE – SETUP.

Figure 5 Sales Contract Price Lines

The result of the setup is a Delivery Invoice batch:

Figure 6 Sales Invoice Batch

Process Order

On the process order production line, a 'Specific Distribution' is entered for the graded size. This distribution is entered for each of the split sizes (3040, 4050, 5060) within the graded size (30405060).

Figure 4 Process Order with Specific Distribution

Partial Delivery

On the Sales Contract, and thus on the Partial Delivery, the unloading size is 30405060.

Figure 5 Partial Delivery with unloading size 30405060

When the Partial Delivery is released, the user can review the size distribution on the transport card. In the example below, the size distribution is according to the input that was given in on the Process Order.

Figure 6 Transport Distribution distributed according to Specific Distribution on Process order

Invoice Batch

When invoicing, the system knows the user wants to invoice on split sizes, because of the matrix on the Purchase Contract. The sizes 3040, 4050 and 5060 are attached to the 30405060 in the Size setup, so the system can split the quantities into the split sizes according to the given distribution on the Process Order.

Figure 7 Invoice Batch split into Split Sizes

Invoice Document

The invoice document looks as follows, this may differ in each company's situation.

Price Corrections

Last modified: 2023-06-06

Introduction

Price corrections can be used to adjust the price of goods. Price corrections are used to correct the bare price to the desired outcome/price. The desired price is the price that includes all the costs added or subtracted to the bare price. Price correction can be applied on both purchase and sales side and can be positive or negative. In addition to the costs or fees for goods, there are costs / fees for transport, packaging, storage, etc. By using price corrections we can for example add costs to bare price of an item. We can do this for example based on the unit of measure of an item, this could be a specific

percentage or amount per kilo. In AGRIO Software, we can include these costs in price corrections. This document explains how price adjustments are used and where they can be set.

Price corrections

These are used for additional costs or fees on the standard price of goods. Examples of price adjustments are the following:

- Custody fees
- Commissions
- Frost packaging
- Grower licenses
- Treatments
- Bagging/ Packaging fee
- NAK costs
- Supplements per week
- Supplements spring
- Weighing costs

Because price adjustments are used in multiple modules in AGRIO Software, price adjustments can be divided into modules. A Module field (1) is used to choose whether a price correction falls under the Purchasing, Sales or Packaging module. Subsequently, AGRIO Software filters per module for the applicable price corrections.

For example, on the purchasing side only price adjustments for purchasing are shown. When setting up packaging, only price adjustments can be selected from the Packaging module.

Even though price corrections are divided into modules, all price corrections are clearly arranged in one screen in the settings of AGRIO Software.

Price adjustments have correction numbers. Correction numbers indicate to which a price correction applies. This can be, for example, invoice number, packaging number or 1x per freight.

A ledger account number can be specified on a price correction. If a general ledger account number is set for a price correction, this is leading for the settlement. If the general ledger account number is not filled, the product posting group is used.

The VAT product posting group indicates which VAT applies. If the VAT product posting group is not populated, the VAT on the Gen. product posting group is used.

Price correction types

In AGRIO Software there exists multiple types of price adjustments Fixed, Matrix, Custody fee, Customer specific.

Fixed

Price corrections with type "Fixed" are price corrections with a fixed price. If this price correction is applied, a fixed amount will be invoiced. This amount can be negative.

If a purchase price correction is positive, the grower gets extra money. If the purchase price correction is negative, the grower gets less money.

The same is true on the sales side. If the sales price correction is positive, the customer pays extra. If the sales price correction is negative, the customer pays less.

Matrix

Price adjustments with type "Matrix" are price adjustments to which a matrix is linked. Depending on one or two variables, a price is determined in the matrix. For example, consider additional price per week per variety.

Price List

When a Price Correction Type of 'Price List' is selected, you may define a Price Correction that retrieves its price from a Price List. Price Lists are preferred of Matrices when more than two variables are needed to determine a price.

Custody fee

Price adjustments with the type "Custody Fee" are price adjustments that apply to the custody fee. These price adjustments can be selected when setting the retention fees in AGRIO Software. These price adjustments only apply to growers.

When a price correction of the type of retention fee is created, in addition to the standard price correction options, there are additional options for setting retention fees. For example, you can choose a start date, an amount per week and a scale per week.

If a price correction with retention fee type exists, then these can be applied to edit orders, after which they will run along to the settlement / invoicing.

Customer specific

Price adjustments with type "Customer-specific" are price adjustments that are made especially for a specific customer. Please contact Newminds for further explanation of customer-specific price adjustments.

It is also possible to select multiple price corrections of different types on for example one sales contract. It is possible to use a fixed price correction and a matrix price correction on for example a sales contract. Paragraph 1.3 this is explained in more detail.

Price corrections per packaging

Price corrections can be set per package. A packaging is selected in the packaging setup and a price correction (1) of the Packaging module is linked to this. The settlement of the price correction can be set as After delivery or After final settlement. It is also decided whether the price correction applies to purchasing, sales or both.

The price correction per package can also be set per contact or per packaging group.

Entering price corrections

Price adjustments can be entered on:

- Purchase / Sales contracts
- Contract types; A price correction linked to a contract type is placed on the purchase or sales contract.

- Matrix
- Partial deliveries

For purchase and sales contracts, price adjustments can be selected on the contract lines by clicking on “No of price corrections”. Here you can select multiple price corrections of different types on one line. These price corrections have to be created in the “price corrections setup” before they can be selected. Depending on the price corrections setup the correction is fixed per 100kg or kilo. If the price correction uses a matrix different variable can be used to determine the correction that has to be applied.

Calculation methods

Potatoes can be sold in a certain packaging, like Big Bags or on Pallets. In Agrio it is possible to define the price corrections (packaging) and how it should be invoiced.

There are 3 options:

- Included in Price
- Separate on Invoice
- Add to Base Price

The customer will buy the potatoes for a certain price, normally the price applies to 100KG. The VAT for food is lower than for materials (like packaging). That is one of the reasons to include the price of packaging in the potato price, because then the VAT for food is applied!

During the creation of a sales contract, the system will validate the base data and add automatically the needed price corrections to the sales contract line. Those price corrections will be considered when creating the sales invoice.

Included in price

It is possible to define for certain price-corrections that the calculation method is “included in price” (1). In this way the customer will not have to pay a high VAT amount for the packaging. The packaging price is then included in the potato price. The VAT used for the potato is then also used for the packaging. Important here, do not fill the VAT Prod. Posting Group on this price correction, otherwise it still applies the higher VAT (2). This is a legal way of working.

On the invoice, in the Included in price option, two lines are made for the price correction. One line is a positive amount and the other line has the same amount but negative. Both lines have the check mark "Do not print on invoice"(2). The customer / supplier does not see that a price correction was included in the basic price, but the accounting still sees this.

Separate on invoice

In the case of using "separate on invoice" (1) the customer must pay for the packaging and the related high VAT% (2). This is material and therefore it will have a high VAT percentage.

The basic price for goods is 10 euros per 100kg (3). A price correction of 2 euros per 100 kg (4) will be added to the invoice separately. In total this gives an invoice price of 12 euros per 100kg. These amounts will be split in the general ledger (5).

Add to base price

In the case of using "add to base price" (1) the price of the packaging will be added to the potato price. Advantage is that the packaging price will be invoiced with the low VAT percentage. Important here, do not fill the VAT Prod. Posting Group on this price correction, otherwise it still applies the higher VAT. This is a legal way of working (2).

The basic price for goods is 10 euros per 100kg. The price correction is 2 euros per 100kg. These two amounts are added together and therefore give a total price for goods of 12 euros per 100kg (3). These amounts are not split in the general ledger, only one line with the total of 12 euros is visible.

Price correction card

At each price correction the default configuration can be defined, like the calculation method and fixed price.

Calculation method - Setup VAT %

For each price correction it should be defined what the VAT% will be when the calculation method is put to "separate on invoice". This can be done at field "Vat Prod. Posting Group (Sep. on Inv.)". There is also the possibility to change the "Gen. Prod. Posting Group".

Thereby, there exists also a field called "VAT. Prod. Posting Group". When the calculation method is "Included in Price" or "Add to Base Price" and the field is empty, the VAT for packaging will use the percentage that is applied for the potato.

A price correction can be used in multiple calculation methods, with this solution it is possible to define which VAT % should be used for each situation.

Print on contract and/or invoice

There exists 2 options at the price correction card, to decide whether a price correction should be printed on the sales contract and/or sales invoice.

The option to print it on the invoice is only relevant for calculation method "Add to base price" and "included in price".

For the option "separate on invoice" it is required to print this information as a row, otherwise the amount is not correct which result in an issue during posting the sales invoice. This will be explained in more detail in the next chapters.

Price correction – PACKAGING

At the price correction card the module packaging can be selected, this can be useful when the correction quantity is set to "packaging qty". This means that the price correction quantity is determined based on the quantity of packaging code (1, 2, 3 or 4).

The PriceUoM value at the price correction card is used for applying the right packaging quantities.

In this example it is set to JUTE25, this means that at the invoice batch the system searches for this value at the related transport order line and if found then the (packaging) quantity is taken over. It does not matter if JUTE25 is defined as packaging 1, 2, 3 or 4.

If the price correction is added to the sales contract line and the PriceUoM value JUTE25 is not defined as a packaging code, then the quantity for above price correction on the invoice batch will be 0.

The price correction as above can be linked to 1 packaging code.

Functional test – Create a Price Correction

Price Correction in the “Setup”(1). Go to the header setup and click on “Price Correction”(2). An overview with all the price corrections created will be shown. Here new price corrections can be created. When creating a new price correction the screen below becomes visible.

In this screen a code (3) for the Price Correction and a description (4) can be created. Then the correction type can be chosen (5). It defines whether the price correction is fixed, a matrix is used, is it for storage or is it customer specific. When the correction type is chosen the calculation method (6) can be selected. How is the price correction calculated, separate on invoice, included in Price or add to the base price.

Then press “ok” and the screen will be displayed. This screen contains the following fields:

- 1 Code: the code that is used for the price correction, when selecting a price correction or for example a sales contract.
- 2 Description: the description of this price correction.
- 3 Module: does the price correction apply on the sales, purchase or packaging side.
- 4 Calculation Method: defines whether the price is, separate on the invoice, included in the price or add to the base price.
- 5 Include in Pool: does this price correction also apply in the pool, yes or no
- 6 Code in Calculation Module: Price Corrections can be added to the price calculation module (other topic), multiple price correction can be summed up and added to one

Calculation Line(s). Therefore the “Code in Calculation Module” has to be entered. If we enter the same code to different price corrections, these price corrections can be summed up to one main price correction that can be added to the calculation lines.

7 Calculation Module only: when this is on “yes” the price correction will be used and is only visible in the price calculation module. This price correction cannot be selected anymore on for example a sales contract under the price correction, but will be added automatically in the calculation module.

8 Correction Type: correction type that is applied, fixed, matrix or customer specific.

9 Fixed/ Matrix Code/ Customer specific: the fixed amount of the price correction, or when a matrix is used it shows the matrix (with different variables for examples week numbers) code applied for this price correction. When the price correction is Customer specific it shows the customer specific price correction applied.

10 Price UOM: the Unit of Measure used for this price correction and the quantity. In this example the fixed price correction is € 3,00 per 100KG.

11 Correction Quantity: shows on which quantity the correction is applied. Is it applied on the gross weight quantity, sorting quantity, or invoice quantity.

12 G/L Account No.: on what G/L account number are the price corrections posted. If only a G/L Account No is used, then it is important that on this G/L Account number the product posting group is set. Otherwise you have to do this (manually) on every invoice when you want to post it.

13 Gen. Prod. Posting Gr.: which product posting group is used for booking a the price correction.

14 VAT Prod. Posting Gr.: which posting group is used for the VAT booking of the price correction.

Functional test – Included in price & Seperate on invoice

Create sales contract in Agrio

Select the right measurement and packaging codes. Click on the three dots after KG (...). In that overview the related packaging codes are visible. Select a row with the right codes and click on "OK".

Based on that information the system knows which price-corrections are attached to those packaging codes.

On the sales contract line, the column "No. of price corrections" is filled.

When clicking on it, the following scheme is shown:

It is possible to change the calculation method, the first one will be put to "included in price".

For both applies that it should be printed on the sales contract and sales invoice, then a sales contract looks like (sales contract, print):

When deactivating the "print on contract" for "Jutesack 25 kg" at the price correction of the related sales contract the result is as follows:

So there are 2 price corrections with each another price correction. For the sales invoice it is important that the setup is correct to apply to right VAT %.

Navigate to "price correction" and open the card for "Jutesack25" and "Paletten":

Jutesack25 is included in price, therefore the VAT at "VAT. Prod. Posting. Group" should be filled ("ERM"= Low) or remain empty. If that field is empty, the VAT of the potato will be applied.

Paletten is separate on invoice, therefore the VAT at "Sep. on Inv" should be filled (VOLL = High)

Create from the sales contract a partial delivery and make sure the transport file is created. When this is done, navigate to "Invoice Batch Sales" (Sales).

Click on "new" and select "new".

The following scheme will pop, click on "ok".

Invoice is created:

The details are visible when opening the invoice:

The price correction "Jutesack 25" is included in the price and therefore they have the same VAT % as the potato "Inovator". The pallet row has a high VAT %, because of the calculation method "separate on invoice" and the related VAT% setup.

Recalculate when something has been changed at the price correction of the related sales contract. To make sure the sales invoice is correct. If so, select "create invoice".

Subsequently, the invoice is created and even a column is displayed whether the row is printed or not (according to the setup). In this example it is not needed to print the rows "Jute Bag 25 KG", because it is included in the price. Only a short remark is enough.

Print the sales invoice:

Result:

It is allowed to delete the sales invoice and change the price correction settings on the related sales contract. Keep in mind that "recalculation" at the sales invoice batch updates the financial aspects (such as the amounts applied) and for example not the adjusted print settings.

Functional test – Add to base price

Create sales contract with 3 price corrections. Print on invoice for "BIGBAGS" is deactivated

Contract looks like (other print screen):

After the partial delivery and transport are finished a sales invoice can be created.

On the Sales invoice the following rows are displayed:

The price of the Big Bag (2,50) has been "added to the potato price" which makes it 57,50 instead of 55. Because the setting "print on invoice" is deactivated, it is not printed on the report.

When activating "print on invoice" for the "Big Bags" the result is:

Setup obligated fields

Last modified: 2025-08-27

Setup obligated fields

In Agrio software, it is possible to set field obligations within a document. This allows you to enforce, at the field level, that certain required fields are filled in before a document can be released.

An example of this is setting an obligation to fill in a purchaser in purchase contracts:

After release:

Conditions:

- The document must be one for which the "release" status exists.

Limitations:

- Despite what the screenshot may suggest, there is no *visual* obligation placed on the field. The asterisk (*) before the value of the "Purchaser code" field is due to the purchasing setting: "Purchaser required."

- No conditional requirements are possible ("If value of field Y = 1, THEN field Z must...").
- No "allowed" values are possible ("Field X must be filled with value '1', '2', or '3'").
- Only certain tables are checked for this. These are indicated with a checkmark "Table check is active" in the table overview. Currently, the following tables are checked:
 - Purchase header
 - Sales header
 - Partial delivery
 - Transport order
 - Processing order
 - Inspection

Configuration

- Go to 'Change Log Setup' / 'Settings for Logging'.
- (Make sure to use the correct Agrio screen, which looks like this:)

- Go to 'Tables' and find the relevant table (in this example: *Purchase Header*).

- Click on the three dots that appear when hovering over the 'Log modification' field with the mouse pointer. Note that the field 'Table Check is active' must be checked, so that this table will be validated.

- Check the field(s) that the software should validate upon releasing the document.

Storage Fee

Last modified: 2023-01-18

Introduction

This Topic describes the functionality of the “Storage Fee”(also known as Storage Premium). Storage fees can be paid to the growers for keeping the Potatoes stored for

a period of time. The potatoes are grown and a few months later harvested and sorted. After sorting, the potatoes are packed and shipped. There can be several weeks between the moment of harvesting, the moments of sorting, the moments of packing and the moments of loading. To bridge these weeks, the potatoes have to be stored. There are costs involved for storing the potatoes. In order to cover these costs, storage fees are paid to the growers by the company that buys the potatoes. These payments are based on the number of weeks of storage and the price applicable for each week. Different types of storage fees may apply, specific agreements with growers can be made about, for example, storage in open air or storage in mechanical cooling.

It is not only about the costs, the company that buys/processed the potatoes also wants to know as soon as possible what its current Lot Inventory is. Therefore, a company can decide/agree with the grower that the storage fees are paid from the moment of reporting back to motivate growers to report back sorting or packaging numbers as soon as possible.

Settings

The storage fee can be setup in the “Agrio Setup”. This is set on the Agrio Setup, because the Storage Fees are not depended on the Sector and/or Segment however, the price correction used for the Storage Fees are dependent on the Sector and/or Segment.

Price Correction for the Storage Fee

A price correction has to be created for the Storage Fee. This price correction can be applied and calculates the storage fee based on the different variables.

When a price correction of the type “Storage” is created, it is mandatory to select the Sector, Segment and Harvest Year to which this correction applies.

Then automatically the Module and the Calculation method are filled in, these cannot be modified. Under “Storage Fees per Price Correction” the different Storage Fees applicable with this price correction can be selected. The price can differ per type of storage fee, Mechanic or Outsideair. These types can have different calculation

methods, per week or per day for example. The starting date of the Storage Fees can be entered and a matrix can be chosen.

Calculation of the days/weeks for the applicable Storage Fee

The price correction indicates whether the calculation of the storage fee is based on days or weeks. If the calculation is based on days, then the storage fee is calculated per day. If the calculation is based on weeks, then the week in which the reporting back has taken place and the week in which the delivery has taken place are taken into account.

The week is determined on the basis of the ISO standards and starts on Monday.

This results in no storage fee being paid for various scenarios:

- Monday reporting back and delivering the same week on Thursday.
- Tuesday reporting back and delivering the same week on Thursday.

The counting of the weeks works as follows:

- Reporting ready in week 46 and delivering in week 51 means $51 - 46 = 5$ weeks storage fee.
- Reporting ready in week 46 and delivering in week 3 means $52 - 46 + 3 = 9$ weeks storage fee.
- If the year has 53 weeks, then an additional week of storage fee is charged for week 53 at the same rate as week 52.

The counting of days / weeks always starts in the day or week after reporting back. So, if the grower reports back in week 43 and delivers in week 44, then a storage fee will be calculated for week 44.

For some organizations it is the case that when a notification is received and delivered on the same day or in the same week, a storage fee must be calculated, namely 1 day or 1 week. This can be set on the segment settings. This setting indicates whether the same day or the same week should also be calculated as 1 day or 1 week.

Multiple Price Corrections on a Contract

The Storage Fees chosen on price corrections are always serial to each other. For example, if there are three storage fees on one price correction, the first Storage fee stops counting as soon as the second Storage fee is given a date on the process order, Etc.

Multiple price corrections can be entered on a purchase contract. Each of these price corrections can contain multiple storage fees. The storage fees within a price correction are calculated serially but the price corrections are calculated independently. So, if there are two storage fee price corrections on the purchase contract, they will be performed in parallel while within them the Storage fees are calculated serially. So, you can get double payment of storage fees in this process.

Process Order Reporting Back Once

For each process order line, a subtable is created that maintains the Storage Fee for that process order line. That table lists the Storage Fee lines as defined in the related price corrections.

The Storage Fee table for a process order line maintains the following information:

- Storage Fee Name; Read-only; Here is the description of the storage fee as defined in the segment settings.
- Date; Here you enter the date that determines from when the relevant storage fee applies for this process order line. Note: If this date is before the start date of the storage fee in the price correction, then the storage fee will start from the start date.
- Amount reported back; Here you enter how much has been reported back. Over this amount the storage fee is calculated.

- End date; This field indicates the end date for the storage compensation. This field is filled in if delivery has taken place by means of partial deliveries or transports or if a subsequent storage compensation has taken place.
- Number of days/weeks; read-only; This field shows the result of the number of days/weeks of storage charges based on date (or start date) and end date.
- Expected; This field shows the expected price from the price correction.
- Previous process order; This field indicates whether the retention allowance line was copied from a previous edit order.

The Storage Fee lines are maintained per process order. When multiple process orders are sequentially to each other on the same lot the storage fee lines are copied to the next process order. This is done to maintain an overview. The user can see in one overview the calculation and history of the storage fee. In addition, the rules are copied to new process orders or deliveries so that the system can calculate the correct values for each delivery.

1. PROCESS ORDER REPORTING BACK MULTIPLE TIMES

Per process order line it can be that the quantities are reported back in multiple times. Both manually and via the Grower Portal. The same way of working is applied as at reporting back once, but then the quantities are reported back in multiple times, this also affects the storage fee.

Applying the Storage Fee

To apply the Storage Fee a price correction has to be set up, for this price correction also a matrix can be used. Below an example of a matrix "OUTSIDEAIR" that is used for the price correction "OUTSIDEAIR" is shown:

Below the Price Correction "PRC.OUTSIDEAIR" is shown, on which also the used matrix is visible.

When a Price Correction is created for the Storage Fee a new purchase contract can be created on which the Price Correction can be selected. On the purchase line the price correction for the Storage Fee can be chosen.

When the right price correction is chosen. The settings of the price correction become available on the price line. Here the Calculation Method “separate on invoice” and the correction type “Storage” are shown with the information of Price Correction for the Storage Fee.

Creating a Process Order including Storage Fee

After the purchase contract is created, a process order can be made for the lot that is purchased. For example a sorting order can be performed. On the process order line the storage fees applicable (based on the price correction on the purchase contract) are visible.

On the new screen opened, the different storage fees are shown including the storage fee code, storage fee type, calculation method, amount, matrix applied (if applied), quantity, start and end date, the number of days/weeks and the status. Only the Storage fees with the status done are invoiced. If for example there is no end-date entered, there will be no checkmark done for that line. Then that Storage Fee will not be settled.

Process order with reporting back once

If on the Process Order 50.000KG is reported back, the storage fee based on the price correction will be calculated for the 50.000KG. This is done based on the report back date 1-10-2020, till the end-date/delivery date 09-10-2020.

When the Process order is finished and a Partial delivery of 50.000KG (reported back quantity) is made on 9-11-2020, to transport the potatoes to the customer the Storage Fee applicable is calculated. Below the created Partial Delivery of 50.000KG is shown.

When the Partial Delivery is finished, the invoice can be made. Below the invoice batch of the Partial delivery (underlying transport) is shown. Here the Storage fee applicable for outside storing in openair is shown. The grower receives in total € 27.000 for the storage of the potatoes, compared to the total purchase price of € 2000,00 the storage fee is significant, this is done on purpose for this topic.

From the invoice batch a Purchase Invoice is created as can be seen below. Here also the purchase price and the storage fee are shown, if we print the invoice, we also see the storage fee on the PDF.

Transport Order

The Storage Fee applicable is also visible on the underlying transport order of the Partial Delivery.

Purchase Invoice Batch multiple Storage Fees

When the transport is finished, the invoicing of the transport can take place. On the invoice (self-billing) also the Storage fees that have to be paid to the grower are visible on the invoice.

If we create a purchase invoice, we see the following details:

On line 1: the number of the item including the description and the quantity

On line 2: the fixed price of € 4,00 per 100KG, the quantity per transport, the total amount (fixed price of € 4,00 per 100KG times the quantity of 35,000

On line 3: The first price correction of the Storage Fee for the storage in Open Air, for the period of time from 11-05-2021 to 17-05-2021. With the total amount of € 105,00

On line 4: The second price correction of the Storage Fee for the storage in a bunker with Mechanical Cooling for the period of time from 11-05-2021 to 17-05-2021. With the total amount of € 35,00

Report settings & translations

Last modified: 2025-09-18

Report Settings & Translations

Report Settings

Report Settings (Setup > General Setup > Communication Mgt - Report > Report Settings)

- General: these reports concern Agrio-specific reports and not standard Dynamics reports.
- Code: the types of reports are divided by codes.
- 700: transport order
- 800: partial deliveries
- 900: invoices
- Description: Name of the report. This can also be translated in the report translations under *Texts*.
- Document category: used for emailing the document. The user can add these categories themselves. A category can be assigned to a user. This determines how the email to them is structured.
- Sector/segment/harvest year: added so that different reports can be generated for these topics.
- Report number: report ID used in the database.
- Background: boolean yes/no whether a background (watermark) is applied to the PDF. When set to “no” and a background is configured in AGRIO settings, that background will be applied. If set to “yes,” it uses the background as configured on this page.
- Report number 2/3: these are report attachments. For example, with a sales invoice, a report can be attached showing where the parties come from (which grower).
- Save as attachment: checkbox for the grower portal. When enabled, the report can be synchronized with the grower portal.
- Portal: indicate whether the report can be synchronized with the portal.
- Save multiple versions: generate a PDF on request. When someone retrieves a PDF in the grower portal, each version they request will be saved. This shows which versions a grower has seen. For example, with a purchase invoice you can check how much a grower still had outstanding at that time.

- Review before publishing: someone must first approve that the document may be forwarded to the grower portal. A tile in the role center shows how many documents still need review.
- Mail salutation text code: standard salutation used in your email.
- Mail body text code: standard text for email body.
- Mail closing text code: standard email closing. If you do not fill in this and the two columns above, Microsoft's default texts will be used, which are available in only a limited number of languages. Ensure these fields are always filled in.
- Mail CC to buyer/seller: must be registered as contacts and linked to the company in the sales/purchase order. This can be specified or linked per report.
- Mail BCC to assigned user ID: this ID can be found, among others, on contracts and partial deliveries.

Attachments Settings

(Settings > General Settings > Processing > Report Settings)

General: define attachments, such as general terms and conditions. By clicking on attachment, you can import a document.

Report Settings (Settings > General Settings > Processing > Report Settings > Texts > Report Settings)

Translations

(Setup> General Setup > Report Settings > Texts > Translation)

General: translation of the report description.

Translations

Translations (Search (Alt + Q) > Document Creator Translations)

By clicking on edit list, different translations can be added, removed, or deleted.

On the left side the tag is shown. If this tag is visible on a report, for example #Containertype, a translation per language code can be added at the bottom.

It is also possible to set specific translations per report by entering a report number after the translation.

Business Central 22

Last modified: 2023-07-12

What's new in Business Central:

Business Central 22:

- Manage user permissions using security groups

You can use Azure Active Directory security groups to manage the permissions users have to access various parts of Business Central.

<https://learn.microsoft.com/en-us/dynamics365/release-plan/2023wave1/smb/dynamics365-business-central/manage-user-permissions-using-security-groups>

- Experience enhanced adaptive cards in Teams

Sharing Business Central records as cards in Microsoft Teams adds context to every conversation and helps people make data-driven decisions. Business Central offers multiple ways to share a record as a card, such as the Share to Teams feature in the web client, pasting a deep link to any page or record in Teams chat, or searching for business contacts directly from within Teams. Our research indicates that the multiple steps required to include a card in a chat message often slows down the pace with which people communicate in chat. This update includes multiple enhancements that make adding a card easier than ever.

<https://learn.microsoft.com/en-us/dynamics365/release-plan/2023wave1/smb/dynamics365-business-central/experience-enhanced-adaptive-cards-teams>

- Menu buttons have been simplified

The Menu buttons Actions and Reports displayed all available buttons which resulted in the presentation of two buttons in the same menu. Action and Reports have been removed and the buttons are available under the right folder.

- Performance - Opening pages is faster

Pages in Business Central have a navigation bar and action bar. We've optimized these areas of the Business Central client so that they run faster and consume less resources. This means customers who use the modern client will get a faster experience.

- We also improved the speed of opening a card from a list.

<https://learn.microsoft.com/en-us/dynamics365/release-plan/2023wave1/smb/dynamics365-business-central/performance--opening-pages-faster>

- Drag and drop files onto the file upload dialog

Business processes often require documents or other files to be captured as part of the system of record. When your file is already at hand, you can save time by dragging that file onto the file upload dialog in Business Central, instead of the more cumbersome navigating through folders in a file picker window. Drag-and-drop experiences are essential to working efficiently. While this enhancement provides a minor boost to productivity and is a convenient alternative, it also puts Business Central on a path toward broader file upload experiences in future release waves.

<https://learn.microsoft.com/en-us/dynamics365/release-plan/2023wave1/smb/dynamics365-business-central/drag-drop-files-onto-file-upload-dialog>

- Access actions and navigation menu efficiently with keyboard

Organizations are looking to streamline their operations through AI, automation, and empowering workers with productivity tools. When time to enter data is critical, every

keystroke and mouse click counts. Business Central adopts the familiar experience from Microsoft 365 applications, such as Excel and Word, to boost efficiency for keyboard users. Access keys with key tips help users quickly explore, navigate, and activate any action in the action bar, navigation menus, and other user interface (UI) elements.

<https://learn.microsoft.com/en-us/dynamics365/release-plan/2023wave1/smb/dynamics365-business-central/access-actions-navigation-menu-efficiently-keyboard>

Business Central 21:

- Extended text functionality for VAT clauses

Users can meet local requirements for long text on VAT clauses.

<https://learn.microsoft.com/en-us/dynamics365-release-plan/2022wave2/smb/dynamics365-business-central/extended-text-functionality-vat-clauses>

- Service declarations F01DGS for Belgium and Intrastat for Italy and France

When required by local authorities, you can report when you export services from one EU country to other EU countries.

- Delegated admins can edit in Excel

Customers often delegate support and administration to their supporting partner. When these delegated administrators need to bulk correct or insert data, Excel is the tool of choice. The add-in now empowers admins to refresh and publish to Business Central, making this a powerful tool for data manipulation.

- Switch companies across environments

Business Central is ready to adapt to the needs of complex SMB organizations by organizing multiple companies across environments. While most employees are bound to a single company, some users need to view, edit, and compare data across companies. The 2022 release wave 2 makes it easier to get an overview of the companies and environments you have access to, and to rapidly switch contexts.

Business Central 20:

- Blocking deletion of G/L accounts

Maintenance of the chart of accounts takes place only a few times, once it's been set up for an organization, but it does occur. To help avoid accidental deletion of general ledger (G/L) accounts, this release wave adds an extra check.

- Block VAT and General Posting Setups

When you start using Business Central with your company's data, you want to get started fast. During the learning phase, you might have made mistakes in how you set up value-added tax (VAT) posting, tax posting, or general posting. Also, company policies might change, resulting in making some posting setups obsolete. Blocking such setups helps users comply with company posting policies. This way, you're assured consistent posting, because only the valid setup can be used.
